Unified Algorithmic Framework for High Degree of Freedom Complex Systems and Humanoid Robots

A Thesis
Submitted to the Faculty
of
Drexel University
by
Daniel Marc Lofaro
in partial fulfillment of the requirements for the degree of
Doctor of Philosophy in Electrical and Computer Engineering
May 2013
To Mommadet and Father. You made me who I am today. You prepared me to become a better man tomorrow. Thank you.
A message to my friends, family and colleagues:

Thank you for spending your time with me. I would not trade our experiences together for anything. You are all truly unique and wonderfully people and deserve the greatest of thanks.

Mommadet, Father, Andrew, Squirt, Aunt Genn, Uncle Matt, Big Bimmel, Momma, Bucky, and Burnidet Dr. Paul Oh, Dr. Youngmoo Kim, Dr. Tom Chmielewski, Dr. Timothy Kurzweg, Dr. Adam Fontecchio DASL: K. Sevcik, C. Korpela, R. Ellenberg, R. Gross, D. Lofaro, A. Alspach, S. Mason, B. Sherbert, J. Hing, K. Yuvraj, P. Brahmbhatt, B. Killen, R. Vallett, Y. Jun, K. Sohn, T. Kim, Jaemi Hubo, M. Orsag, D. Castley; ECE: Moshe, Tanita, Kathy, Amy, Delores, Chad, Tai, Dan, Wayne, Scott, Alyssa, Dave, Manu, MET Lab and the rest of the ECE Dept. Friends: Kevin, Jess, Liz, Sharon, Rob, MLE, Rachel, Nate, Sandy, Keyur, Trey, Shoko, Jon, and the rest of the Elite Gang; Louis, Maggie, Duck, Carl, Caroline, Chris, Alex, Bella, Andrew U., Ttalg, Sarah, Mayank, Will, and the rest of the Goon Squad. Korea: Dr. Lee, Dr. JH Oh, Inhyeok, Jungwoo, Chelsea, Hubo-Lab, Woojin, Kayla, Jonghee, Meejin, Mahin; Special Thanks to: Jaemi Hubo, Leoben, Dirc, Simon Cavil, D’Anna, Caprica, Aaron, Mini-0, Shoko Robot.
A message to everyone:

Robots are people too.

List of Figures

2.1 Timeline of Daniel M. Lofaro’s research from 2008 to 2012 ...................... 13

2.2 Hubo2 Plus platform: 40 DOF, 130 cm tall full-size humanoid robot weighing 37 kg. .............................................................................. 21

2.3 Mini-Hubo platform: 22 DOF, 46 cm tall miniature-size humanoid robot weighing 2.9 kg. ................................................................. 23

2.4 OpenHubo model of the Hubo2 humanoid robot developed by the Drexel Autonomous Systems Lab and runs using the open-source robot simulation environment OpenRAVE[16]. ................................................................. 23

3.1 Hubo-Ach simple block diagram showing multiple controllers in multiple processes. Diagram also shows that Hubo-Ach works with the RP, T&E and V&V stages seamlessly. ................................................................. 26

3.2 Feedback loop integrating Hubo-Ach with ROS................................. 27

3.3 Histograms of Ach and Pipe messaging latencies. Benchmarking performed on a Core 2 Duo running Ubuntu Linux 10.04 with PREEMPT kernel. The labels $\alpha$/ $\beta$ indicate a test run with $\alpha$ sending processes and $\beta$ receiving processes[20]................................................................. 30

3.4 Timing diagram of Hubo-Ach. All times $t_*$ denote measured times each block takes to complete. Tests were done on a 1.6Ghz Atom D525 Dual Core with 1GB DDR3 800Mhz memory running Ubuntu 12.04 LTS linux kernel 3.2.0-29 on a Hubo2+ utilizing a CAN bus running at 1Mbps baud. Average CPU usage is 7.6% using a total of 4Mb or memory. ...................... 32

3.5 The amount of time it takes to request and get the reference for the actuators. In this case each sample has a time step of 0.005 sec .......................... 36

3.6 The amount of time it takes to complete all unread commands given by the user via the console. In this case each sample has a time step of 0.005 sec 36
3.7 The amount of time it takes to send the external trigger. In this case each sample has a time step of 0.005 sec ............................................ 37

3.8 The amount of time it takes to process the built in filter. In this case each sample has a time step of 0.005 sec ............................................ 37

3.9 The amount of time it takes to set the reference on the actuators via setting the data in the CAN bus buffer. In this case each sample has a time step of 0.005 sec ........................................................... 38

3.10 The amount of time it takes to request and get the actual position from the actuators. In this case each sample has a time step of 0.005 sec ........... 38

3.11 The amount of time it takes to request and get the IMU data. In this case each sample has a time step of 0.005 sec ...................... 39

3.12 The amount of time it takes to request and get the accelerometers data. In this case each sample has a time step of 0.005 sec ......................... 39

3.13 The amount of time it takes to request and get the force-torque sensors. In this case each sample has a time step of 0.005 sec ......................... 40

3.14 The amount of time it takes to set the state data on the feedback channel. In this case each sample has a time step of 0.005 sec ......................... 40

3.15 CPU utilization for the Hubo-Ach process when 1) idle, 2) under open-loop control, 3) reading the sensors, and 4) under closed-loop control. It is important to note that the cpu utilization stays within 0.3% when idle and under closed loop control. This means that the CPU utilization of Hubo-Ach is independent of the external control method. Thus it will not add more to the CPU load under complex control schemes then under simple ones. ............................................................... 42

3.16 The commanded reference plotted against the actual reference recorded via Hubo-Ach and ground truth via CAN analyzing utilities. In this plot the commanded reference is not automatically filtered by Hubo-Ach. The commanded joint is the right shoulder pitch. The model of the joint $G(s)$ is also plotted. The resulting bandwidth is 45.79 rad/sec or 7.29 hz. ............. 43
3.17 The commanded reference plotted against the actual reference recorded via Hubo-Ach and ground truth via CAN analyzing utilities. In this plot the commanded reference is not automatically filtered by Hubo-Ach. The commanded joint is the right shoulder pitch. The model of the joint $G'(s)$ is also plotted. The resulting bandwidth is $66.98 \text{ rad sec}^{-1}$ or $10.66 \text{ hz}$. 

3.18 Reference $\theta_r$ being applied to Hubo via Hubo-Ach. $\theta_r$ is set on the Feed-Forward channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle.

3.19 Desired reference $\theta_d$ being filtered before applied to Hubo via Hubo-Ach. $\theta_d$ is sent through a filter that reduces the jerk on the actuator then the new reference $\theta_r$ is set on the FeedForward channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle.

3.20 The commanded reference plotted against the actual reference recorded. In this plot the commanded reference is automatically filtered by Hubo-Ach.

3.21 $\theta_r$ plotted against $\theta_c$ and $\theta_a$ recorded via Hubo-Ach with values for $L$ ranging from 0 to 400 in increments of 20.

3.22 Desired reference $\theta_d$ being filtered before applied to Hubo via Hubo-Ach. $\theta_d$ is sent through a filter that reduces the jerk on the actuator by using Equation 3.8. The new reference $\theta_r$ is set on the FeedForward channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle. This method adds compliance to the system.

3.23 $\theta_r$ plotted against $\theta_c$ and $\theta_a$ recorded via Hubo-Ach using the feedback filtering method.

3.24 $\theta_r$ plotted against $\theta_c$ and $\theta_a$ recorded via Hubo-Ach using the feedback filtering method with different moments applied to the joint. You will note that as the moment increases so does $\theta_{fb\text{filter}}$.

3.25 Block diagram of Hubo-Ach being used for the DRC event #7, valve turning. The process to get the Hubo to turn a valve consists of loading a model of the Hubo and the valve into the simulator. OpenRAVE is used as the simulator using the OpenHubo model of Hubo. The trajectory planner uses CBiRRT to plan a collision free statically stable joint space path. Once the planning is completed the resulting joint space trajectory it is sent through a low-pass filter then sent to the Hubo.
3.26 Hubo (left) turning a valve via Hubo-Ach alongside Daniel M. Lofaro (right). Valve turning developed in conjunction with Dmitry Berenson at WPI for the DARPA Robotics Challenge. ........................................ 55

3.27 Desired reference $\theta_d$ being filtered before applied to Hubo via Hubo-Ach. $\theta_d$ is sent through a filter that reduces the jerk on the actuator by using Equation 3.8. The new reference $\theta_r$ is set on the FeedForward channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle. This method adds compliance to the system ........................................ 56

3.28 Denavit-Hartenberg diagram showing that axis of rotations and displacements to create the transform in Equation 3.10. $\alpha$ is the angle between the axis of rotation of joint $n$ and $n - 1$ about the of $n$. $\theta$ is the angle between the axis of rotation of joint $n$ and $n - 1$ about the axis perpendicular to the axis about $n$. ................................................................. 58

3.29 Hubo2+ coordinate frame for use with the forward and inverse kinematic example. These coordinate frames are defined specifically for the IK and FK examples and are the same frame as in[44] ......................... 59

3.30 Hubo2+ coordinate frame for right arm. Uses with the forward and inverse kinematic example. These coordinate frames are defined specifically for the IK and FK examples and are the same frame as in[44] ................. 60

3.31 Hubo preforming 6-DOF IK in real-time using method discussed in Section L.0.4 .......................................................................................................................... 67

3.32 Independent validation of Hubo-Ach via Zucker et. al.[12] work in Continuous Trajectory Optimization for Autonomous Humanoid Door Opening ......................................................................................... 68

4.1 OpenHubo model of the Hubo2 humanoid robot developed by the Drexel Autonomous Systems Lab and runs using the open-source robot simulation environment OpenRAVE[16]. (Left) Shell Model - High polygon count. (Right) Collision model - Made with primitives. .............................. 88
4.2 Diagram of how the OpenHubo simulator is connected to Hubo-Ach. No changes to previous controllers are required for them to work with the simulator. Just as before the desired reference $\theta_d$ being filtered before applied to Hubo via Hubo-Ach. $\theta_d$ is sent through a filter that reduces the jerk on the actuator then the new reference $\theta_r$ is set on the FeedForward channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle. At this point $\Gamma_{ts}$ is set high and the OpenHubo simulator reads $\theta_e$. The reference is set within OpenHubo and solved with a simulation period of $T_{sim}$. Once The state, $H_{state}$ has been determined it is placed on the Hubo-Ach FeedForward channel and the ready trigger $\Gamma_{fs}$ is raised. Hubo-Ach is waiting for the rising edge of $\Gamma_{fs}$ to continue on to the next cycle. ................................................................. 90

4.3 Hubo and OpenHubo walking using Hubo-Ach in Real-Time and Sim-Time Respectively ................................................................. 91

5.1 Hubo model diagram for ZMP walking in the $x$ direction (side view). $b$ and $f$ are the step lengths for the left and the right foot. $A$ defines the ankle. $t_1$ is the time of the starting of the step, $t_2$ defines the landing of the stepping foot. $P$ defines the hip location. $\tilde{x}$ defines the walking velocity. The middle diagram depicts the SSP and the left and right diagrams show the DSP................................................................. 100

5.2 Hubo model diagram for ZMP walking in the $y$ direction (front view). $A_R$ and $A_L$ defines the left and right ankles respectively. $t_1$ is the time of the starting of the step, $t_2$ defines the landing of the stepping foot. $t_0$ defines time when the stepping foot is at peak step height. $P$ defines the hip location. $\tilde{y}$ defines the body sway velocity. The middle diagram depicts the SSP and the left and right diagrams show the DSP............................................ 101

5.3 Joint space walking pattern. The trajectory sampling period $T$ is 0.005 sec. Forward step length is 0.2 m, sway velocity $\tilde{y}$ is 0.062 m/sec, and step period is 0.8 sec. ................................................................. 102
5.4 Diagram of how the OpenHubo simulator is connected to Hubo-Ach and is used to run a walking trajectory. The walking pattern generator ensures proper constraints on the velocity, acceleration and jerk and thus the filter seen in Fig. 4.2 is not desired. $\theta_r$ is set directly on the FeedForward channel thus each joint will have the response as seen in Fig. 3.16 for each commanded reference command at each time step. Hubo-Ach reads the FeedForward channel and commands Hubo at the rising edge of the next cycle. At this point $\Gamma_{ts}$ is set high and the OpenHubo simulator reads $\theta_c$. The reference is set within OpenHubo and solved with a simulation period of $T_{sim}$. Once the state, $H_{state}$ has been determined it is placed on the Hubo-Ach FeedForward channel and the ready trigger $\Gamma_{fs}$ is raised. Hubo-Ach is waiting for the rising edge of $\Gamma_{fs}$ to continue on to the next cycle. In order to keep with the sim-time the Walking Pattern also waits for the rising edge of $\Gamma_{fs}$ to put the next desired reference on the FeedForward channel. ................................................................. 103

5.5 Virtual Hubo in OpenHubo preforming ZMP walking using Hubo-Ach in sim-time based on the walking pattern generated in Section 5.1.1.............. 104

5.6 Virtual Hubo in RobotSim preforming ZMP walking using Hubo-Ach in sim-time based on the walking pattern generated in Section 5.1.1.............. 104

5.7 Diagram of how the OpenHubo simulator is connected to Hubo-Ach and is used to run a walking trajectory. The walking pattern generator ensures proper constraints on the velocity, acceleration and jerk and thus the filter seen in Fig. 4.2 is not desired. $\theta_r$ is set directly on the FeedForward channel thus each joint will have the response as seen in Fig. 3.16 for each commanded reference command at each time step. Hubo-Ach reads the FeedForward channel and commands Hubo at the rising edge of the next cycle. At this point $\Gamma_{ts}$ is set high and the OpenHubo simulator reads $\theta_c$. The reference is set within OpenHubo and solved with a simulation period of $T_{sim}$. Once the state, $H_{state}$ has been determined it is placed on the Hubo-Ach FeedForward channel and the ready trigger $\Gamma_{fs}$ is raised. Hubo-Ach is waiting for the rising edge of $\Gamma_{fs}$ to continue on to the next cycle. In order to keep with the sim-time the Walking Pattern also waits for the rising edge of $\Gamma_{fs}$ to put the next desired reference on the FeedForward channel. ................................................................. 105
5.8 Diagram of how the RobotSim simulator is connected to Hubo-Ach and is used to run the walking trajectory. The walking pattern generator ensures proper constraints on the velocity, acceleration and jerk and thus the filter seen in Fig. 4.2 is not desired. \( \theta_r \) is set directly on the **FeedForward** channel thus each joint will have the response as seen in Fig. 3.16 for each commanded reference command at each time step. Hubo-Ach reads the **FeedForward** channel and commands Hubo at the rising edge of the next cycle. At this point \( \Gamma_{ts} \) is set high and the RobotSim simulator reads \( \theta_e \). The reference is set within RobotSim and solved with a simulation period of \( T_{sim} \). Once The state, \( H_{state} \) has been determined it is placed on the Hubo-Ach **FeedForward** channel and the ready trigger \( \Gamma_{fs} \) is raised. Hubo-Ach is waiting for the rising edge of \( \Gamma_{fs} \) to continue on to the next cycle. In order to keep with the sim-time the Walking Pattern also waits for the rising edge of \( \Gamma_{fs} \) to put the next desired reference on the **FeedForward** channel.

5.9 Reference \( \theta_r \) being applied to Hubo via Hubo-Ach. \( \theta_r \) is set on the **FeedForward** channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle.

5.10 Hubo2+ preforming ZMP walking using Hubo-Ach in real-time based on the walking pattern generated in Section 5.1.1.

5.11 Hubo2+ preforming ZMP walking in place using Hubo-Ach in real-time based on the walking pattern generated in Section 5.1.1 with a forward velocity of \( 0.0 \text{ m/sec} \).

5.12 The \( (x, y, z) \) work space position of the objet is found via HSV tracking. The rotation error \( \theta_e \) and distance of the object from the projection of the robot onto the ground \( X_e \) is sent to the *walking planner*. The walking planner decides if it has to turn or walk forwards. The robot will stop when it is within \( 0.2 \text{ m} \) of the object and facing it within an error of \( \pm0.02 \text{ rad} \).

5.13 3D Object tracking using HSV color matching and an RGB-D camera to gain depth information.

5.14 Hubo using Hubo-Ach to walk and track a blue box. The robot will walk towards the blue box until it is within \( 0.2 \text{ m} \) at which point it will stop. If the box moves, the robot will turn to track the box.

5.15 Using feedback from the force-torque sensors the Hubo-Ach controller adds compliance to the legs via active damping.
E.1 Number of degrees of freedom for robots form 1929 to the present. ........ 137

F.1 DARPA Robot Challenge Events. Pictures depict the Hubo2+ (KHR-4) preforming the eight given tasks. The photographs are meant to help you imagine that the robot is capable of preforming these tasks. The events are - Event 1: Driving an un-modified human vehicle; Event 2: Walking over rough, un-even terrain; Event 3: Removing debris from regions of interest; Event 4: Opening and navigating through multiple doors and hallways; Event 5: Climb an industrial ladder; Event 6: Break through a wall using un-modified human tools; Event 7: Turn a valve; Event 8: Replace a pump (note: this was replaced by a hose insertion task). All photographs were staged and taken by Daniel M. Lofaro. Picture montage taken from Dr. Paul Oh’s meeting to DARPA at the DRC Kickoff meeting, October 23-25, 2012.[63] ........................................................ 139

G.1 Example of the zero moment point on a bipedal robot in a single support phase (bottom) and a double support phase (top). If the zero moment point, the location of the center of mass (COM) projected in the direction of gravity, is located within this support polygon then the system is considered statically stable...................................................... 141

H.1 Hubo modeled as a single inverted pendulum with COM located a distance \( L \) from .......................................................... 144

H.2 Block diagram of the balance controller used to balance Hubo in this work. 145

H.3 Hubo Balancing using method discribed in Section H ........................ 145

I.1 Hubo dynamic walking using Hubo-Ach as the primary controller. The standard ZMP walking algorithms were implemented by our partners Mike Sillman and Matt Zucker at Geortia Gech and Swarthmore respectively. All control was implemented using Daniel M. Lofaro’s Hubo-Ach system... 146

K.1 Hubo successfully throwing the first pitch at the second annual Philadelphia Science Festival event Science Night at the Ball Park on April 28th, 2012. The game was between the Philadelphia Phillies and the Chicago Cubs and played at the Major League Baseball stadium Citizens Bank Park. The Phillies won 5-2...................................................... 155

Abstract:

The degrees of freedom (DOF) of robots and complex systems have been increasing exponentially since the early 20th century. Today it is common place for complex control systems to have 40 DOF. This number is projected to be 70 DOF by the year 2020. Robots with high DOF allows for complex tasks such as tool manipulation, greater human-robot interaction and agile full-body locomotion. More DOF require greater attention to local communication delays, bandwidth, system configuration and stability. In addition different tasks being performed by separate parts of the robot in tandem bring on greater issues including controller timing and priorities. The increase in DOF on single system requires that the traditional methods of controller design be re-examined.

This dissertation describes a Unified Algorithmic Framework for High Degree of Freedom Complex Systems and Humanoid Robots that allows a user to develop controllers using a three tier infrastructure. The Unified Algorithmic Framework called Hubo-Ach is a multi-process based system that allows for robust multi-rate simultaneous control and seamless implementation between virtual, miniature, and full-size robots with no modification. The three tier infrastructure provides different levels of cost to entry and testing. Examples of this field tested framework functioning on simulated, miniature, and full-size high DOF robots is given as well as validation by external researchers.
1. Introduction

The degrees of freedom (DOF) of robots and complex systems have been increasing exponentially since the early 20th century. Today it is common place for complex control systems to have 40 DOF. This number is projected to be 70 DOF by the year 2020 (see Section E). Robots with high DOF allows for complex tasks such as tool manipulation[1–4], greater human-robot interaction such as music performances[5–8] and agile full-body locomotion[9–11]. More DOF require greater attention to:

- local communication delays
- system configuration
- bandwidth
- stability

In addition different tasks being performed by separate parts of the robot in tandem bring on greater issues including controller timing and priorities. The increase in DOF on a single system requires that the traditional methods of controller design be re-examined.

Experimental results in kinematic planning (Section J), end-effector velocity control (Section K) and human-robot interaction[8] resulted in specific additional requirements for a high DOF controller for complex systems and humanoids. These requirements include:

- Robust controller integration
- Live control
- High gain position controlled joints move without creating an over torque condition
- Synchronous control
- Run on onboard computer
- Run in real-time
• Allow for hardware out of the loop testing

This work describes the creation of a controller architecture for high DOF robots that achieves all of the above requirements. The system is call Hubo-Ach and has the following key attributes:

• Real-Time Performance

• Inherently robust controller integration via multi-process architecture

• No-Head of Line Blocking scheme (newest data first)

• Low CPU usage (lean and mean, written in C)

• Compatible with almost any simulator

• C/C++, Python and Matlab bindings

• Built-in real-time networking support (up to 1khz)

• Maximum limiting bus bandwidth

• Robot agnostic

Hubo-Ach is verified via comprehensive experiments. It is validated via third party implementation.

The Hubo-Ach system is described in detail in Section 3. Full documentation on usage and programming examples of Hubo-Ach is given in Section 4. Verification of Hubo-Ach performance is given in Section 5. Third party validation of Hubo-Ach performance is given by Zucker et. al.[12], O’Flasherty et. al.[13], and Section I. Finally a survey of 17 independent Hubo-Ach users showing overwhelming positive results is given in Section M.
This document shows that the verified and validated Hubo-Ach system is truly a *Unified Algorithmic Framework for High Degree of Freedom Complex Systems and Humanoid Robots* because of its ability to combine a verity of control algorithms on a robot agnostic system.

### 1.1 Critical Gap

Due to the high entry cost for high DOF robots the Hubo-Ach controller should be able to be tested on low/no *cost to entry* systems. This means the controller must be compatible with:

- virtual/simulated robot
- full-size robot
- kinematically scaled robot

It is evident that the critical gap is needing a *unified algorithmic framework for high degree of freedom robots that allows for development on multiple platforms*. This unified algorithmic framework connects the three robots above in the *Three Tier Infrastructure*\[14\] for complex system development as described in Section 1.2. The idea for this infrastructure was first realized by a Partnerships for International Research and Education (PIRE) grant #0730206, sponsored by the the U.S. National Science Foundation (NSF). This is the same grant in which this work is sponsored. The three tiers include:

- Rapid Prototype (RP) phase with zero cost to entry (OpenHubo Platform Section 2.4.3)

- Test and Evaluation (T&E) phase with low cost to entry (Mini-Hubo Platform Section 2.4.2)
Verify and Validate (V&V) phase with lease-time cost to entry (Hubo Platform Section 2.4.1)

The unifying algorithmic framework called Hubo-Ach[1] is described in Section 3.

As described above this work demonstrates that a multi-process, multi-rate control structure coupled with the proper timing mechanisms is conducive to creating this unified algorithmic framework. Through verification and validation Hubo-Ach is shown to be a viable unifying algorithmic framework conducive to collaborative work. A road map of how this work began is shown in Section 2.1.

An example of the three tier infrastructure being used to enable a high DOF robot to throw a ball is given in Section K. The methods used include a unique algorithm for end-effector velocity control called Sparse Reachable Maps (SRM) is explained in Section K.1. In addition an end-effector velocity control method is used in a live throwing experiment at a baseball game and described in Section L.1.

The Hubo-Ach system is verified under many circumstances including:

- Real-time closed form inverse kinematic controller (Section 3.6)
- Full body locomotive task of turning a valve (Section 3.6.1)
- Full body locomotive task of walking (Section 5.1.2)
- Visual seroving while performing full body locomotive task (Section 5.2)
- Active damping via force-torque feedback (Section 5.3)

Hubo-Ach is then independently validated by other researcher through the examples of:

- Door opening (Section 3.8)  
- Dynamic walking (Section I)
A study/survey about how well the Hubo-Ach system performs as a *unifying algorithmic framework* is given. Results and the questions are given in Section M.

Lastly Section 6 discusses the results of the work and the future of this system.

*Note:* This work has already been validated by peers in the field through:

- Use as the primary control system for the DARPA Robotics Challenge Track-A Team DRC-Hubo, Section F.
- Used in the NSF-PIRE\(^1\) and NSF-MIRR\(^2\) projects.
- Various research being conducted using Hubo-Ach at MIT, WPI, Purdue, Ohio State, Swarthmore College, Georgia Tech, and Drexel University.

In addition more information on *why this problem is hard* is in Section 1.3.

For the remainder of this document the focus will be on implementing this Unifying Algorithmic Framework on the different platforms of the three tier infrastructure. These platforms are Hubo, Mini-Hubo, and OpenHubo. Detailed description of each of these robots are available in Section 2.4.

### 1.2 Three Tier Infrastructure

The three tier infrastructure allows for:

- Rapid Prototype (RP) phase with zero cost to entry (OpenHubo Platform Section 2.4.3)
- Test and Evaluation (T&E) phase with low cost to entry (Mini-Hubo Platform Section 2.4.2)

---

\(^1\)NSF-PIRE: Partnerships for International Research and Education (PIRE) #0730206, sponsored by the the U.S. National Science Foundation (NSF)

\(^2\)NSF-MIRR: Major Research Infrastructure Recovery and Reinvestment (MIRR) #CNS-0960061 sponsored by the the U.S. National Science Foundation (NSF)
• Verify and Validate (V&V) phase with lease-time cost to entry (Hubo Platform Section 2.4.1)

The OpenHubo[15] kinematic and dynamic model in OpenRAVE[16] is the RP for this document. The T&E phase is a miniature kinematically scaled structure to that of the Hubo platform. Mini-hubo[14] acts as the model for the T&E phase. The Hubo platform[17] is used as the full-size humanoid for this infrastructure. A key aspect is that a single controller commands all three of the phases. This controller is called Hubo-Ach and is described in Section 3. Fig 1.1 shows the three tier infrastructure for the Hubo platform.

The key point of the three tier infrastructure is allowing for testing on the RP. When the algorithms applied to RP works, moving to the T&E phase is the next step. If it does not work in T&E then the cycle states movement back to the RP phase. If it does work then movement to the V&V phase is the next step. If application to V&V is not successful then the cycle states movement back to T&E or RP phase. If it does work then the project is complete [14].

1.3 Challenges

This problem is hard when each controller has different frequencies, timing requirements (asynchronous vs. synchronous), latency restrictions, newest state data is more important than older state data and most basic of all languages the controller is written in. This is especially true for complete and complex autonomous systems. I define a complete and complex autonomous system as an electro mechanical mechanism with high degree of freedom (DOF) that is capable of making its own decisions through the use of sensor data processed by its artificial intelligence (AI). The combination of high DOF and the requirement for autonomy makes the work space broad and controllers complex. The overarching question becomes; What is the control
Figure 1.1: Three tier infrastructure. Tier 1: Rapid Prototype (RP) using OpenHubo. Tier 2: Test and Evaluation (T&E) using Mini-Hubo. Tier 3: Verify and Validate (V&V) using Hubo.
system structure for a complete and complex autonomous systems with high DOF, a multitude of sensors, AI performing high-level and low-level tasks all while keeping a stable system structure conducive to collaborative work? Current methods of solving the problem of controller synchrony and latest state data is to keep your critical control elements in the primary control loop. Inter-process communication (IPC) and/or network sockets to communicate between the high level and low level processes even if written in different languages. The majority of IPC have the problem of head of line blocking (HOL) which means you must read the older data in a buffer before you read the newest data. In the computer science field this is not a problem because all data being intact is typically desired. In the field of robotics and control the most recent state data is more important to a real-time control system to act on. This thesis shows that by expanding on the idea of multi-process controllers connected to high-speed low-latency IPC you can create a robot layer on a computer platform that will allow low-level controllers to run in separate processes while still allowing them access to the most recent data as the priority. The new technical idea is the robot layer, a control layer that allows external processes to run like normal and not deal with the specifics of the given robot system. The robot system can be replaced by a simulated system without any of the processes needing to be modified or even know of the change. This allows more mature controllers to be easily interfaced with this system without modifying control rates or timing. This robot layer must be:

- Have a IPC latency much less then that of the robot’s inherent sampling period
  \[ t_{\text{ipc}} \ll T_r \]

- Allow for command rates much slower then the inherent sampling period \[ T_{\text{slow}} \gg T_r \]

- Allow for command rates much faster then the inherent sampling period \[ T_{\text{fast}} \ll \]
1 Introduction

\( T_r \)

- Allow for arbitrary command rates.
- Allow for real-time and non-real-time controllers to command actuators
- Allow for all processes to have access to the newest data first
- Allow for no more than one real-time step delay between command and robot actuator retrieval
- Commanded such that it is for an arbitrary robotic actuator.
- Triggering for process synchronization
- Triggering for simulator synchronization and holding

We can succeed now not only because the bleeding edge technology allows for the fast enough communication between processes with access to the latest data.

Results are measured quantitatively and qualitatively. Data showing proper loop rates, timings, controller implementation, simulation connections etc. show the viability of the system. User survey shows methodology is sound, useful, and practical.

1.4 Contributions and Vertical Leap

The primary contributions and vertical leap to the field is the creation of a unified algorithmic framework for high degree of freedom complex systems and humanoid robots. The resulting framework allows seamless integration of:

- Controllers running at different loop rates
- Runs on multiple robots with no modification
- Runs on simulated robots with no modification
• Inherent structure makes it more robust

• Written in C for controller programing language interdependence (use C bindings in desired language)

The unified algorithmic framework Hubo-Ach is an Open-Source BSD licensed software allowing for open use.

The contributions of Hubo-Ach have been independently verified by external parties[12, 13]. It has been validated by multiple IEEE publications[2, 3], in review for a publication in the IEEE Robotics and Automation Society Magazine (RAM)[1] and has been the top featured video on the IEEE Spectrum Video Friday article on December 14th, 2012[18].
2. Background and Results from Preliminary Experiments

This section gives a brief background and results from preliminary experiments of the methods used to complete the Hubo-Ach system. The motivation and timeline of experiments is given in Section 2.1. Different control system structures are discussed in Section 2.2. Section 2.3 describes why inter-process communication (IPC) is used for the Hubo-Ach control system and as well as a brief background of different IPC methods. Section 3 gives this background in greater detail. Finally Section 2.4 describes the different platforms used to validate Hubo-Ach the *Unified Algorithmic Framework for High Degree of Freedom Complex Systems and Humanoid Robots*.

2.1 Motivation

This section provides context to the origin of the idea of a unified algorithmic framework for complex systems called Hubo-Ach.

In summer 2008 Daniel participated in the NSF-EAPSI (East Asian and Pacific Summer Institute) allowing him to study at the Hubo-Lab at KAIST to learn how to maintain, operate and program the Hubo series robot. In Fall of 2008 Daniel started his work on a Hubo KHR-4 model in the Drexel Autonomous Systems Lab (DASL) at Drexel University. Shortly after that in Spring of 2009 he had the robot performing interactive musical tasks such as listening to music and autonomously tapping its hand to the beat[8]. This was the first of many experiments in sensor integration on the Hubo. Later that spring Daniel and the rest of DASL showed Hubo to the public at a live demonstration at the Philadelphia Please Touch Museum. In winter of 2009 the first of the visual feedback methods was implemented [10]. In 2010 Daniel investigated brain machine interfacing with the robot as well as multi-modal sensing
using visual and auditory cues[7]. In late 2010/early 2011 Daniel started on his first throwing experiments which culminated in making the Hubo robot throw the first pitch at a Major League Baseball game[9]. A timeline of Daniel’s work can be seen in Fig. 2.1.

Throughout this work Daniel quickly realized that there was no simple and robust way of integrating controllers on top of the existing Hubo control system. Hubo’s original control system was written by Hubo-Lab in the Windows environment utilizing the Real-Time Extension (RTX) for Windows API. This controller is a typical single loop, single process, real-time controller that gets its high level input via flags and data fields located in shared memory. As the controller gets more complex it became more and more probable that something would throw a fault. If one part of the controller failed the whole system fails.

The Daniel worked with the Drexel Autonomous Systems Lab to create a linux based controller for the Hubo called ACES/Conductor. This controller designed by Sherbert et. al.[19] is a multi-threaded real-time controller that breaks each joint into individual devices. Each of these devices has multiple layers including the hardware, control, and command layer. Each of these layers runs their own real-time loop, sharing data via pointer passing for dynamic memory fields. Though the theoretical concept for this controller was sound, proper implementation would be suitable for an FPGA, GPU or other processors with many cores. Because each device had multiple real-time loops associated with it (one for each layer) and there are many devices (joints) on the Hubo the CPU usage was high. When running on a dual core 1.6 Ghz Intel Atom Processor a constant 100% CPU usage was recorded. This did not allow other processes to run in tandem. In addition there was an inherent memory leak in the dynamic memory. This was brought about from the system never being able to guarantee that another thread is not using a block of memory, thus it is never
Figure 2.1: Timeline of Daniel M. Lofaro’s research from 2008 to 2012
trashed. This caused the memory usage to increase at a predictable rate. This would cause a complete system crash when the memory size surpassed the available memory of the system. It was found that this system was not suitable to run the Hubo robot.

Learning from the past experiences Daniel sought out to create a controller that could:

- handle high degrees of freedom
- runs in real-time
- simple sensor integration
- low CPU usage

This goal was realized with the creation of Hubo-Ach as described in Section 3. Further examples of why Hubo-Ach was created can be found in Appendix K.

### 2.1.1 Human Robot Interaction Preliminary Experiments

The initial goal was to have a humanoid robot become an interactive musical participant with humans. This spawned the creation of a visual method of tracking the beat in the absence of auditory cues[8]. This came from a modification of a method of allowing children to play interactive games with humanoid robots[10]. The resulting method was effective, but to increase the accuracy it was required to combine a pre-existing auditory beat tracker with the visual system. This culminated with a multi-process system that combine the auditory and visual beat trackers[5–7]. A human comparison was completed and found that this combined method was as accurate at detecting the beat in music as average humans.

**Results from preliminary experiments**

When collaborating with other to create a complex robot control systems integrating controllers is difficult because of the use of:

- different loop rates causing synchronization issues
• different programming languages making using the same libraries a challenge

It was found that it is best to keep each working systems *independent* allowing them to run at their native rate and on their native platforms[20].

### 2.1.2 High Degree of Freedom Kinematic Planning Preliminary Experiments

The next challenge was to perform kinematic planning for end effector velocity control. This resulted in the development of a method that is able to solve inverse kinematics (IK) for high degree of freedom (DOF) systems where there is no closed-form solution as well as create collision free trajectories for high DOF robots[15]. This is described in detail in Section L and K. This culminated in the verification and validation of the system by an experiment where Hubo full-size humanoid robot throw the first pitch at a Major League Baseball (MLB) game[9, 21].

**Results from preliminary experiments**

As best practice when controllers and planners are implemented it is important that low-level controllers such as balance and obstacle avoidance run at all times[1]. Non-priority controllers such as throwing trajectory planning can run in the background in a separate process. Keeping the processes separate allowed the system to be more resistant to lag and crashes of one or more of the controllers. This brought validation to the overarching plan for the unified algorithmic framework for complex systems and humanoid robots.

### 2.1.3 Lessons Learned

At this point creating these experiment it was required to *hacked* together pre-existing systems that allowed the robot to do the task. This is the point where it
was realized that a unified algorithmic framework for complex systems and humanoid robots was required for further development in the field. Key lessons learned from these experiments were:

- Must inherently decouple controllers loop rates and phases
- Must allow for collaborators not have to inject their code into existing source.
- Must work with multiple robots for testing, evaluation, validation, and verification.

This is where Hubo-Ach was born. The idea was to create a multi process architecture for humanoid control using state of the art high-speed low-latency Inter-Process Communication (IPC) techniques[1]. This is different from traditional IPC techniques because of the lack of head of line (HOL) blocking and focus on low-latency. Section 3.2 gives further details and comparisons of different IPCs.

The need for this unified framework was amplified when the Hubo was chosen to be the primary platform for the DRC-Hubo\textsuperscript{1} Track-A team. Since its initial conception Hubo-Ach has become a fully functional system used in active research by multiple universities including MIT, WPI, Purdue, Ohio State, Swarthmore College, Georgia Tech, and Drexel University[2, 3]. This research also acts as a key source of verification and validation of the system.

### 2.2 Control System Structures

The traditional single loop control structure that is used in robot control software such as Orocos[22], Microsoft Robot Studio[23], RobotC[24], MATLAB[25] and LabVIEW[26] are not suited for high DOF robots. Due to the nature of these highly

\textsuperscript{1}DRC-Hubo: http://www.drc-hubo.com/
redundant complex electrical mechanical system it is common to desire multiple different controllers running in tandem. Different controllers are needed when the system is in different states or doing different tasks or performing multiple tasks at the same time. Combining these controllers is a problem in complex system. This problem is hard when each controller has different loop rates that are not even multiples of one another, timing requirements (asynchronous vs. synchronous).

Multi-threaded approaches using shared memory allow for compatibility of multiple loop rates such as in Lee et. al.[27] with multi-threaded controllers on their humanoids, Rai et. al.[28] with multi-threaded controllers on their snake robots and Zheng et. al.[29] with multi-threaded controllers on their under water robots. The multi-threaded approach still has an inherent flaw. If the parent or one of the other controller threads crashes it is difficult or impossible to restart the controller and still have access to the shared memory.

By using a multi-process approach allows controllers to fault and restart with minimal effect on the other controllers. Typical ways of communicating between different processes is via UDP or TCP/IP such as OpenHRP[30] with their server based control platform for the HRP humanoid robot; Aramaki et. al.[31] and Lofaro et. al.[7] with their multi-computer based control methods and the popular Robot Operating System (ROS)[32] by Willow Garage.

Communicating via TCP/IP sockets, such as in OpenHRP and ROS, guarantee that the data is received but it does not guarantee an arrival time. This means if the checksum fails the message will be sent again increasing the latency of the message. This does not work well if a real-time control loop is required. Using UDP does not resend if the checksum fails. This keeps the latency low and is better for real-time applications such as in the work of Lofaro. Both UDP and TCP/IP require that the buffer is read before new data is read. This means that you must read the older data
before newer data. This is called head of line blocking or HOL[20].

Newer state information is preferred by robots that work in the physical world over older data. Thus it is desired that HOL is eliminated. This can be done with some forms of inter-process communication (IPC).

OpenHRP and Webots[33] are two of the very short list of systems that have simulators that use the same controller as the hardware platforms. However at this time to the best of our knowledge there is no system that:

- uses the same controller with the software and hardware systems
- is inherently robust by using a multi-process approach
- uses low-latency methods for controller communications

2.3 Multi-Process and Interprocess Communication

This section gives a quick background to why inter-process communication (IPC) is used for the Hubo-Ach control system and a brief background of different IPC methods. Section 3 give this background in greater detail.

The idea for a Control Architecture for High DOF robots stems from a gap in physical implementation of control algorithms for robot hardware. The simplest approach to developing robot software is to integrate all functionality in one program. This functionality includes the following controllers:

- Hardware Control
- Perception
- Planning
- Kinematics
- etc.

If all of this functionality is in one process then it has the benefit of freedom of inter process communication latency. However being in one process also means that
if one of the controllers lags or faults it cause the entire controller to lag or fault. This is of great concern if a non-priority controller such as vision processing faults causing a priority controller such as a balance controller, to fail. This will cause the robot to fall. How is this fixed? One solution and my proposed solution is to use multiple processes and IPC methods. Inter-process communication is a method of exchanging data between multiple processes. Typical POSIX methods give you the \textbf{oldest} information first and have locks on the memory when processes are writing to it. An overview of these mechanisms are given in [34].

Robots work in the physical world. More recent information is more important to it then older. In most cases it is acceptable to know the most recent data and never read any of the older data. This would happen if your sensors update at a faster rate then that of the robot. Typically robot actuators have a bandwidth much much lower then that of a modern computer. If sensor information is shared using traditional shared memory over POSIX methods the controller would have to read the older information before it reaches the information it is most interested in, the newest data. This is known effect but new concern for robot controllers called head of line blocking[20].

It is desired to make a multi-process controller that can share data between multiple processes with low-latency and no head of line blocking. There are a few IPCs that offer no head of line blocking and low-latency. A description of each IPC type is in Section 3. Table 3.2 shows a full comparison of the different IPC types.

My thesis Hubo-Ach is a multi-process control system that uses IPC methods to communicate between processes. Section 3 describes Hubo-Ach in detail.

\section*{2.4 Platforms}

This section describes the different platforms that are focused on in this document.
2.4.1 Hubo2 Plus

The Hubo2 Plus series robot is a 130 cm (4’ 3”) tall, 42 kg (93 lb) full-size humanoid commonly refereed to as Hubo. The Hubo series was designed and constructed by Prof Jun-Ho Oh at the Hubo Lab in the Korean Advanced Institute of Science and Technology (KAIST) in Daejeon, South Korea [35]. Hubo has 2 arms, 2 legs and a head making it anthropomorphic to a human. It contains 6 degrees of freedom (DOF) in each leg, 6 in each arm, 5 in each hand, 3 in the neck, and 1 in the waist; all totaling 38 DOF. All joints of the major joints are high gain PID position controlled with the exception of the fingers. The fingers are open-loop PWM controlled. The sensing capability consists of a three axis force-torque (FT) sensor on each leg between the end of the ankle and the foot as well as between the arm where it connects to the hand. Additionally it has an inertial measurement unit (IMU) at the center of mass and accelerometers on each foot. The reference commands for all of the joints are sent from the primary control computer (x86) to the individual motor controllers via two Controller Area Network (CAN) buses. There are currently eight Hubo’s functioning in the United States as of December 2012. Jaemi Hubo is the oldest of the Hubos in America and has been at the Drexel Autonomous Systems Lab \(^2\) (DASL) since 2008 [36]. Fig. 2.2 shows the major dimensions of Hubo. Table 2.1 shows the other attributes of the Hubo.

A full-scale safe testing environment designed for experiments with Jaemi Hubo was created using DASL’s Systems Integrated Sensor Test Rig (SISTR) [37]. Additionally all algorithms are able to be tested on miniature and virtual versions of Jaemi Hubo prior to testing on the full-size humanoid through the creation of a surrogate testing platform for humanoids [38].

2.4.2 Mini-Hubo

Mini-Hubo[14] is a miniature version of the Hubo platform describe in Section 2.4.1. It is used as the Test and Evaluation (T&E) stage of the three tier infrastructure described in Section 1.2. Mini-Hubo is kinematically scaled to the Hubo platform. The attributes of the Mini-Hubo system are in Table 2.2. The robot is shown in Fig. 2.3.

2.4.3 OpenHubo

OpenHubo[39] is an open-source kinematic and dynamic simulator for the Hubo2 and Hubo2+ series robots. It was developed by the Drexel Autonomous Systems Lab and runs using the open-source robot simulation environment OpenRAVE[16]. Fig. 2.4 shows the OpenHubo model. Table 2.3 shows the specifications of OpenHubo.
Figure 2.3: Mini-Hubo platform: 22 DOF, 46 cm tall miniature-size humanoid robot weighing 2.9 kg.

3. Hubo-Ach: A Unified Algorithmic Framework for High DOF Robots

This section describes in detail the [unified algorithmic framework for high degree of freedom complex systems and humanoid robots](#). An overview of the system is given in Section 3.1. Timing and system testing is given in Section 3.3 Validation examples are given in Section 3.5, 3.6 and 3.6.1. Verification of Hubo-Ach from independent parties is given in Section 3.8 and results from surveys about the system is given in Section M.

3.1 Overview

Hubo-Ach \(^1\) is an [multi-process unified algorithmic framework](#) for high degree of freedom complex systems and humanoids. In this case specifically Hubo. This provides a conventional GNU/Linux programming environment, with the variety of tools available therein, for developing applications on the Hubo. It also efficiently links the embedded electronics and real-time control to popular frameworks for robotics software: [ROS](http://www.ros.org) \(^2\), [OpenRave](http://openrave.org) \(^2\) and [MATLAB](http://www.mathworks.com) \(^3\).

Reliability is a critical issue for software on the Hubo. As a bipedal robot, Hubo must constantly maintain dynamic balance; if the software fails, it will fall and break. A multi-process software design improves Hubo’s reliability by isolating the critical balance code from other non-critical functions, such as control of the neck or arms. For the high-speed, low-latency communications and priority access to latest sensor feedback, Ach provides the underlying IPC. Fig. 3.1 shows a block diagram with multiple controllers in multiple processes communicating with Hubo-Ach. The diagram also shows that Hubo-Ach works with the RP, T&E and V&V stages seamlessly.

---

\(^1\)Available under permissive license, [http://github.com/hubo/hubo-ach](http://github.com/hubo/hubo-ach)

\(^2\)[OpenRave]: [http://openrave.org/](http://openrave.org/)

Hubo-Ach handles CAN bus communication between the PC and embedded electronics. Because the motor controllers synchronize to the control period in a phase lock loop (PLL), the single hubo-daemon process runs at a fixed control rate and communicates on the bus. The embedded controllers lock to this rate and linearly interpolate between the commanded positions, providing smoother trajectories in the face of limited communication bandwidth. This communication process also avoids bus saturation; with CAN bandwidth of 1 Mbps and 200Hz control rate, hubo-daemon currently utilizes 78% of the bus. Hubo-daemon receives position targets from a feedforward channel and publishes sensor data to the feedback channel, providing the direct software interface to the embedded electronics.

Each Hubo-Ach controller is an independent processes. The controllers handle tasks such as balance, manipulation, and human-robot interaction. Each controller asynchronously reads state from the feedback Ach channel and sets reference positions in the feedforward channel. Huobo-daemon reads the most recent reference position from the feedforward channel on the the rising edge of its control cycle. This allows the controller processes to run at arbitrary rates without effecting the
PLL of the embedded motor controllers or the CAN bus bandwidth utilization.

Figure 3.2 shows an example control loop integrating Hubo-Ach and ROS. The `hubo-daemon` communicates with the embedded controllers at 200Hz, publishing to the `feedback` channel. The `hubo-ach-ros` process bridges ROS topics and Ach channels. It translates messages on the `feedback` Ach channel to the `rFeedback` ROS topic and translates the `rFeedforward` ROS topic to the `ref` Ach channel. The `planner` process computes desired trajectories, which are relayed via `hubo-ach-ros` to `filter` for preprocessing to smooth the motion and reduce *jerk* before `hubo-daemon` communicates references to the embedded controllers. During operation, `rviz` displays a 3D model of the Hubo’s current state. This is important because it allows for simple human feedback and diagnostics.

All of the above process runs asynchronously, communicating at different rates; however, `hubo-ach-daemon` maintains its 200Hz cycle, ensuring phase lock with the embedded controllers. This control loop effectively integrates real-time IPC and control under Hubo-Ach with the non-real-time ROS environment.

Hubo-Ach is being verified and validated through use in numerous projects at several research labs. In addition it is getting real-world validation by being the projects primarily revolve around the DARPA Robot Challenge (DRC)\textsuperscript{4} team DRC-

\textsuperscript{4}DARPA Robot Challenge: http://www.theroboticschallenge.org/
Hubo\textsuperscript{5}. The DRC includes rough terrain walking, ladder climbing, valve turning, vehicle ingress/egress and more. Figure 3.26 shows the Hubo using the Hubo-Ach system to turn a valve.

Hubo-Ach provides an effective base for developing real-time applications on the Hubo. Separating software modules into different processes increases system reliability. A failed process can be independently restarted, minimizing chance of damage to the robot. In addition, the controllers can run at fast rates because Ach provides high-speed low-latency communication with \texttt{hubo-daemon}. Hubo-Ach provides a C API that is easily called from high-level programming languages and integrates with popular platforms for robot software such as ROS and MATLAB, providing additional development flexibility. Hubo-Ach is a validated and easy to use interface between the mechatronics and the software control algorithms of the Hubo full-size humanoid robot.

### 3.2 Inter Process Communication Comparision

POSIX provides three main types of IPC: streams, datagrams and shared memory. A review of each is made before making a choice for desired message passing scheme.

**Streams:**
The IPC type \textit{stream} includes pipes, FIFOs, stream sockets, and TCP sockets. All stream based methods suffer from head of line (HOL) blocking which means older data \textbf{must} be read before newer data. For robotic applications we must be able to access the newest data immediately and read older data if needed. This is a different paradigm than typical streaming application because robots are real-time sensitive meaning the newest information holds more value to the overall system than the older data.

\textsuperscript{5}DRC-Hubo Homepage: http://drc-hubo.com/
Datagrams:

POSIX datagrams come in two major flavors, datagram sockets and POSIX message queues. Datagram sockets are less likely to block the sender then streams. The most important reason why datagrams are not a good solution for my application is that newer messages are lost if the buffer is filled. Newer data is more important than older data in my control system thus this is not a viable option.

POSIX message queues are similar to datagrams sockets with the addition of message priorities. Unlike datagram sockets if the buffer fills the POSIX message queues will block. This will cause the application to stop processing until it is able to read/flush the old messages. Thus similar to other methods mentioned this also suffers from HOL.

Shared Memory:

POSIX shared memory is very fast and allows access to the latest data by simply writing over a variable. Though I have been advocating that the newest information is the most important, old information can not be discarded. If using POSIX shared memory there is no way of recovering older data that might have been missed by a controller.

What is needed is a method of sharing data that is non-blocking and as low-latency like shared memory, but still holds older data and uses an asynchronous IO scheme. The asynchronous IO scheme is required so the controller is not locked to a set rate by the data transaction method. N. Dantam et. al.[20] shows that Asynchronous IO (AIO) might be appropriate for this application however the implementation under Linux is not as mature as I require. In addition N. Dantam shows that other IPC mechanism using select/poll/epoll/kqueue are widely used network server and help mitigate but not totally removed the issue of HOL. The primary problem being that thought the sender will not block the reader must still read the oldest data first.
The question now is what IPC mechanism will be suitable for my control system.

Upon investigation three major mechanisms are available; Robot Operating System (ROS)[32], Message Passing Interface (MPI)[41] and Ach[20]. Though ROS is ubiquitous in the robotics and automation field the inherent latency and the non real-time (RT) guarantee due to the use of TCP/IP it is not a good choice. MPI is ubiquitous in the high-performance computing field. It has full non-blocking capabilities and is geared towards maximizing message throughput for networked clusters[20]. Table 3.2 shows a comparison of a wide range of IPC methods. A focus on reducing latency is not given. Ach does focus on latency. Fig. 3.3 shows histograms of Ach and Pipe messaging latencies. Benchmarking performed on a Core 2 Duo running Ubuntu Linux 10.04 with PREEMPT kernel. The labels αs/βr indicate a test run with α sending processes and β receiving processes[20].

### 3.3 Timing

To ensure that the Hubo-Ach controller is able to run at the desired control rates, timing experiments of each part of the controller was taken. All tests were done with a sample step size of 0.005 sec. Each of the following figures have the same X and Y scale. This is to give a visual representation of how much each portion of the cycle each part of Hubo-Ach takes up.

Fig. 3.5 shows the amount of time it takes to request and get the reference for the actuators. This reads the most recent reference off of the feedforward channel and uses that as the reference used in this cycle of Hubo-Ach. This time is measured to be 0.0010 ms with micro-second accuracy. The standard deviation is 0.0028.

Fig. 3.6 shows the amount of time it takes to complete all unread commands given by the user via the console. User commands are manual actions such as homing individual or all joints, resetting actuator errors, and reading error states. This time
Figure 3.4: Timing diagram of Hubo-Ach. All times $t_i$ denote measured times each block takes to complete. Tests were done on a 1.6Ghz Atom D525 Dual Core with 1GB DDR3 800Mhz memory running Ubuntu 12.04 LTS linux kernel 3.2.0-29 on a Hubo2+ utilizing a CAN bus running at 1Mbps baud. Average CPU usage is 7.6% using a total of 4Mb or memory.
is measured to be 0.011 ms with micro-second accuracy. The standard deviation is 0.0033.

Fig. 3.15 shows the amount of time it takes to send the external trigger. This external trigger tells a controller or simulator when the new reference’s and commands have been read. In real-time mode the measured time delay is 0.0014 ms with micro-second accuracy and a standard deviation of 0.0035.

Fig. 3.8 shows the amount of time it takes to process the built in filter. This filter has multiple options:

- Direct reference mode where the filter acts as a reference pass through (Section 3.5.1).
- Low pass filter based on previous reference commands (Section 3.5.2).
- Low pass filter using feedback from the actual position of the joint (Section 3.5.4).

③⑤⑦⑨④
• Compliance amplification mode which artificially increases the compliance of the joint (Section 3.5.3) The measured time delay is 0.0080 ms with micro-second accuracy. The standard deviation is 0.0030 ms.

This gives the system the option of reducing the jerk on the high-gain position controlled actuators allowing for slower update rates on the reference channel. The direct reference mode allows a controller to have direct access to the commanded reference with no additional filtering.

Fig. 3.9 shows amount of time it takes to set the reference on the actuators via setting the data in the CAN bus buffer. The amount of time it takes for the for the references to be set to the actuators via the CAN is dependent on the baud rate of the CAN bus. Currently the baud rate is set to 1Mbps. CAN is the limiting factor in the loop rate. The table of the required bits to be sent via can is available in Table 3.3.

Fig. 3.10, 3.11, 3.12, 3.13 shows the amount of time it takes to request and get the state data from the actuator from over the CAN bus. This takes in total 1.365 ms plus an additional 3.0 ms for wait-on-CAN to ensure all queued messages in the CAN buffer are send and received.

Fig. 3.14 shows the amount of time it takes to set the state to the feedback channel. The measured delay is 0.092 ms with a standard deviation of 0.091.

Assuming no CAN delays Hubo-Ach can run at 1900 khz. With the current configuration of a 2 channel CAN bus it is restricted to below 237 hz. With a 4 channel CAN configuration it can be increased to 469 hz. With an 8 channel CAN configuration it can be increased to 1063 hz.

3.4 CPU Usage

The CPU usage was analized while the Hubo-Ach controller was being used in the following states:

• Idle
• Under open-loop control
• Reading the sensors
• Under closed-loop control

Fig. 3.15 shows the result of this test. The results confirm that the CPU utilization stays within 0.3% when idle and under closed loop control. This means that the CPU utilization of Hubo-Ach is independent of the external control method. Thus it will not add more to the CPU load under complex control schemes then under simple ones. This makes it easy to model Hubo-Ach in when adding it to a CPU usage budget.

Figure 3.15: CPU utilization for the Hubo-Ach process when 1) idle, 2) under open-loop control, 3) reading the sensors, and 4) under closed-loop control. It is important to note that the cpu utilization stays within 0.3% when idle and under closed loop control. This means that the CPU utilization of Hubo-Ach is independent of the external control method. Thus it will not add more to the CPU load under complex control schemes then under simple ones.

3.5 Verification Experiments

This section contains step by step verification examples showing the controller for high DOF complex system functions properly with the hubo system. All controllers are implemented using the multiple processes approach and includes all latencies found in Section 3.3.

3.5.1 Joint Space Step Response

This section shows the experimental and expected results of controlling a single joint via the Hubo-Ach system. In this example the right shoulder pitch (RSP) is given a step input from 0.0 rad to 0.4 rad. The reference position $\theta_r$ is begin recorded as well as the actuator setpoint $\theta_c$ and the actual position of the joint $\theta_a$. These definitions are also available in Table 3.4.

Fig. 3.16 shows the results when a step input is applied and Hubo-Ach is in $\text{HUBO\_REF\_MODE\_REF}$ also know as pass-through mode. This sets the what the desired reference on the FeedForward Hubo-Ach channel to the actuator’s reference, i.e.:

$$\theta_c(N) = \theta_r(N)$$  \hspace{1cm} (3.1)

From the results of Fig. 3.16 a 2nd order model $G(s)$ of the joint can be made.
Figure 3.16: The commanded reference plotted against the actual reference recorded via Hubo-Ach and ground truth via CAN analyzing utilities. In this plot the commanded reference is not automatically filtered by Hubo-Ach. The commanded joint is the right shoulder pitch. The model of the joint $G(s)$ is also plotted. The resulting bandwidth is $45.79 \text{ rad sec}^{-1}$ or $7.29 \text{ hz}$. 
\[ G(s) = \frac{1120}{s^2 + 85s + 2800} \]  

(3.2)

From the bandwidth can be determined to be 45.79 rad/sec or 7.29 hz. The control loop is over an order of magnitude greater then the actuator’s bandwidth thus the control rate is acceptable.

Have knowledge this specific system, it is known that the acceleration is artificially limited in the controller when starting from rest on this model of Hubo motor driver. Thus the system is non-linear. If the initial rate limiting is not taken into account and a focus is put to matching the slope of the middle. The new model \( G^*(s) \) is:

\[ G^*(s) = \frac{2200}{s^2 + 115s + 5500} \]  

(3.3)

It now has a bandwidth of 66.98 rad/sec or 10.66 hz. This is still well within the Hubo-Ach bandwidth. The step response of \( G^*(s) \) can be found in Fig. 3.17.

Fig. 3.18 shows the block diagram of the control setup.

As seen in Fig 3.16 \( \theta_c \) tracks \( \theta_r \) perfectly. As expected \( \theta_a \) lags by a minimum of 1 time step \( T \). This is the time it takes between sending \( \theta_c \) to the actuator over the CAN bus plus the time it takes in receiving the feedback from the encoder of the motor over CAN. The remainder of the lag is due to the rise time of the actuator. This is different for each joint. Because all major joints are high-gain PID the rise-time and overshoot is very small which makes the robot very stiff. The total lag between commanding the joint on the FeedForward channel and the response of the actuator is:

\[ t_{\text{lag}} = t_{\text{filter}} + t_{\text{rise}} \]  

(3.4)
Figure 3.17: The commanded reference plotted against the actual reference recorded via Hubo-Ach and ground truth via CAN analyzing utilities. In this plot the commanded reference is not automatically filtered by Hubo-Ach. The commanded joint is the right shoulder pitch. The model of the joint $G^*(s)$ is also plotted. The resulting bandwidth is $66.98 \text{ rad sec}^{-1}$ or $10.66 \text{ Hz}$.

Figure 3.18: Reference $\theta_r$ being applied to Hubo via Hubo-Ach. $\theta_r$ is set on the FeedForward channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle.
### 3.5.2 Joint Space Step Response with Position Filtering

Giving a step input to a high-gain PID position controlled actuator can cause an over current fault, burn out motor drivers, strip gears due to the *jerk* etc. To reduce this effect Hubo-Ach has multiple modes of on-board filtering. These modes are:

- Reference Input Filtering
- Compliance Amplification

This section talks about *reference input filtering* as a method to apply a step input each joint in joint space and limit the jerk. It is important to note that the obvious answer is to reduce the PID gains to make the robot *more compliant* however the goal of this work is to make a fully functional system that does not require modification of the robot. In this case the PID gains are set by the motor drivers and that is considered to be a part of the robot. In future firmware updates of the motor drivers we will have the ability to change PID gains on the fly.

*reference input filtering* uses the history of the previous $\theta_c$ sent to the given actuator. The current commanded actuator position $\theta_c(N)$ is given by:

$$
\theta_c(N) = \frac{\theta_c(N-1) \cdot (L - 1) + \theta_r(N)}{L}
$$

(3.5)

Where $L$ is an integer that represents the length of the filter and $L \geq 1$. If $L = 1$ then Equation 3.5 becomes Equation 3.1.

Fig. 3.20 shows the commanded reference plotted again the actual reference using the filtered mode defined in Equation 3.5. Fig. 3.21 shows the $\theta_r$ plotted against $\theta_c$ and $\theta_a$ for different values of $L$. It is easy to see that as $L$ increases the $t_{rise}$ also increases and the *jerk* is reduced.

This method is a feed-forward method that assumes that the position you set the actuator to is the actual position of the actuator.
Figure 3.19: Desired reference $\theta_d$ being filtered before applied to Hubo via Hubo-Ach. $\theta_d$ is sent through a filter that reduces the jerk on the actuator then the new reference $\theta_r$ is set on the FeedForward channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle.

Figure 3.20: The commanded reference plotted against the actual reference recorded. In this plot the commanded reference is automatically filtered by Hubo-Ach.
3.5.3 Compliance Amplification

Compliance amplification takes advantage of the internal compliance of the joints and amplifies that by feeding back the PID error $\theta_e$. Like the Equation 3.1 we have no past information about the set reference and we have only the compliance given by the joints. If we think about $\theta_e$ and what effects it we can use it to add compliance to our system. It is important to note that because the Hubo is a high-gain PID position controlled device with an integral gain $K_i$ set to zero the steady state error of the joint (the PID error $\theta_e$) is proportional to the moment applied to the joint. If we combine the reference $\theta_r$ and $\theta_e$ multiplied by a compliance gain $K_c$ we are able to add/amplify the compliance to the system.

$$\theta_e(N) = K_c\theta_e(N) + \theta_r(N)$$

(3.6)
It is important to note that $K_c \leq 1$ or the system will go unstable. If $K_c = 1$ then we have

$$\theta_c(N) = \theta_a(N)$$

(3.7)

### 3.5.4 Joint Space Step Response with Feedback Filtering

Feedback filtering allows us to remove the requirement that we know the joint’s current position. Similar to Equation 3.5 this method sets $\theta_c$ based on a filter length $L$ and the current desired value $\theta_r$. However instead of assuming that we know all past $\theta_r$ we use the actual position $\theta_a$. This method adds compliance in a similar way to that of Section 3.5.3.

$$\theta_c(N) = \frac{\theta_a(N) \cdot (L - 1) + \theta_r(N)}{L}$$

(3.8)

This causes three major effects:

**Effect 1:** The movement of the joint is guaranteed to be filtered even if the previous reference is unknown.

**Effect 2:** The steady state error of the feedback filtering method $\theta_{e_{fbfilter}}$ is greater than that of the PID error $\theta_e$ in the direction of the moment acting on the joint.

$$\theta_{e_{fbfilter}} > \theta_e$$

(3.9)

**Effect 3:** The joint’s compliance has increased due to the effect of the moment applied to the joint on the steady state error.

Fig. 3.23 shows $\theta_r$ plotted against $\theta_c$ and $\theta_a$. $\theta_a$ not only lags behind $\theta_c$ but it also has a greater steady state error. Fig. 3.24 shows how the steady state error $\theta_{e_{fbfilter}}$ increases with an applied moment. This is where we get our compliance.
Figure 3.22: Desired reference $\theta_d$ being filtered before applied to Hubo via Hubo-Ach. $\theta_d$ is sent through a filter that reduces the jerk on the actuator by using Equation 3.8. The new reference $\theta_r$ is set on the FeedForward channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle. This method adds compliance to the system.

Figure 3.23: $\theta_r$ plotted against $\theta_c$ and $\theta_a$ recorded via Hubo-Ach using the feedback filtering method.
Figure 3.24: $\theta_r$ plotted against $\theta_c$ and $\theta_a$ recorded via Hubo-Ach using the feedback filtering method with different moments applied to the joint. You will note that as the moment increases so does $\theta_{fbfilter}$. 
3.6 Kinematics

Kinematic planning is a key focus of the Hubo-Ach controller. This section provides two published examples of the Hubo-Ach controller being used for inverse kinematics and control. Section 3.6.1 shows the work of Lofaro et. al. [3] using Constrained Bi-Directional Rapidly-exploring Random Tree (CBiRRT) to provide a statically stable joint space trajectory allowing the robot to turn a valve. Section 3.7 shows the work of Lofaro et. al. [2] using traditional 6 DOF forward and inverse kinematic techniques to provide an analytical IK solution to each of the 6 DOF end effectors. The additional use of on-line trapezoidal velocity profiling methods in Section L.0.5 allow for the creation of a real-time IK controller based in Hubo-Ach.

3.6.1 Valve Turning

This section presents progress towards performing valve turning task set by the DARPA Robotics Challenge (DRC) Event #7[42]. This work is published verification of the Hubo-Ach system with details in Lofaro et. al. [3]. The task requires that a robot locate, approach, grasp, and turn an industrial valve with two hands. A core constraint for the DRC is that communications with the robot are limited, making conventional tele-operation is infeasible. Thus, the valve-turning task requires a straightforward way for a user to command the robot to perform complex actions.

Fig. 3.25 shows the block diagram of Hubo-Ach being used for the DRC event #7, valve turning. The process to get the Hubo to turn a valve consists of loading a model of the Hubo and the valve into the simulator. OpenRAVE is used as the simulator using the OpenHubo model of Hubo. The trajectory planner uses CBiRRT to plan a collision free statically stable joint space path. Once the planning is completed the resulting joint space trajectory it is sent through a low-pass filter then sent to the Hubo. Fig. 3.26 shows the Hubo turning a valve using this method.
Planning

The planning package plans trajectories for high degree of freedom robots so that they can perform object manipulation. The initial configuration of the robot is critical to manipulation because the robot must be able to:

- reach and manipulate the object for the entirety of the desired trajectory,
- maintain balance during execution,
- avoid self-collisions and collisions with the environment

Motion planning is provided by the Constrained Bi-Directional Rapidly-exploring Random Tree (CBiRRT), an efficient and probabilistically complete manipulation planning suite. CBiRRT consists of three main components: constraint representation, constraint-satisfaction, and a general planning algorithm. For full details of CBiRRT and its implementation, see Berenson et. al.[43].
Experiment

Our preliminary experiments with the Hubo were centered around validating our method of motion planning for the robot and evaluating the robots capabilities in relation to the requirements of our DRC task (turning the valve). These tests were performed on the Hubo2+ at MIT and Drexel University, housed in the lab of Professor Russ Tedrake and Paul Oh respectively. Our experiments confirmed that the planning system enabled control of the Hubo and that the Hubo was physically capable of turning the valve. A full description of our methods and experiment can be found in [3].

Figure 3.27: Desired reference $\theta_d$ being filtered before applied to Hubo via Hubo-Ach. $\theta_d$ is sent through a filter that reduces the jerk on the actuator by using Equation 3.8. The new reference $\theta_r$ is set on the FeedForward channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle. This method adds compliance to the system.

3.7 Six Degree of Freedom Inverse Kinematic Implementation Example

This section shows how we calculate the inverse kinematics (IK) for the Hubo’s right arm and how we use that calculation in conjunction with Section 3.5. The result is the ability to command the end effector (EEF).

In order to control the Hubo’s upper body manipulators in work space as opposed to joint space both forward and inverse kinematics are required, (FK) and (IK) respectively. In order to find a proper solution the joint limits, singularities and feasible workspace (no-self collisions) must be accounted for.

The kinematic structure of the right and left arm of the Hubo are identical with the caveat that the work space offset is mirrored over the z-axis. This means that they have the same Denavit-Hartenberg (DH) parameters.

### 3.7.1 Forward Kinematics

The transform between joint adjacent joints is represented by the transform:

\[
T_{i-1}^{i} = \begin{bmatrix}
\cos(\theta_i) & -\sin(\theta_i)\cos(\alpha_i) & \sin(\theta_i)\sin(\alpha_i) & a_i\cos(\theta_i) \\
\sin(\theta_i) & \cos(\theta_i)\cos(\alpha_i) & -\cos(\theta_i)\sin(\alpha_i) & a_i\sin(\theta_i) \\
0 & \sin(\alpha_i) & \cos(\alpha_i) & d_i \\
0 & 0 & 0 & 1
\end{bmatrix}
\]  

(3.10)

Where \( \theta_i, \alpha_i \) and \( d_i \) are shown in Fig. 3.28. The coordinate frame of the Hubo2+ used for both the forward and inverse kinematics are defined in Fig. 3.29 and Fig. 3.30. The DH parameters for the arm for the transform \( T_{i-1}^{i} \) is found in Table 3.6.

In order to calculate for full FK transform \( T_N^E \), where \( E \) represents the end-effector and \( N \) is the neck (robot origin), we must first calculate:

\[
T_0^6 = \prod_{i=1}^{6} T_{i-1}^{i} = T_0^1T_1^2T_2^3T_3^4T_4^5T_5^6
\]

(3.11)

In order to procure the transform \( T_N^E \) we must pre-multiply \( T_0^6 \) by the transform \( T_N^0 \) and post-multiply it by the transform \( T_6^E \). This results in transform \( T_N^E \):
Figure 3.28: Denavit-Hartenberg diagram showing that axis of rotations and displacements to create the transform in Equation 3.10. \( \alpha \) is the angle between the axis of rotation of joint \( n \) and \( n-1 \) about the of \( n \). \( \theta \) is the angle between the axis of rotation of joint \( n \) and \( n-1 \) about the axis perpendicular to the axis about \( n \).

Image Credit:

Figure 3.29: Hubo2+ coordinate frame for use with the forward and inverse kinematic example. These coordinate frames are defined specifically for the IK and FK examples and are the same frame as in [44].
Figure 3.30: Hubo2+ coordinate frame for right arm. Uses with the forward and inverse kinematic example. These coordinate frames are defined specifically for the IK and FK examples and are the same frame as in [44]
\[
T_N^E = T_N^0 T_0^6 T_6^E
\]  \hspace{1cm} (3.12)

Where \(T_N^0\) is

\[
T_N^0 = \begin{bmatrix}
0 & 0 & 1 & l_{A1} \\
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
\]  \hspace{1cm} (3.13)

Now with a given set of joint space angles we can find the end-effectors position in reference to the robot origin, the neck.

### 3.7.2 Inverse Kinematics

The next step is to find the inverse kinematic (IK) solution for the right arm. Inherently this problem has multiple solutions. When solving the IK Pieper[45] states that a closed-form solution does exist if:

- Three consecutive joints axes of the manipulator are parallel to one another

OR

- Three consecutive joints intersect at a single point

The kinematic structure in Fig 2.2 and Fig 3.29 shows that the Hubo2+ platform does have a three joints that intersect the same point in the shoulders and in the hips. Thus a closed-form solution exists for both arms and both legs.

The transform \(T_0^6\) in Equation 3.11 is needed to solve the IK problem for the shoulder. It is important to note that \(T_0^6\) is in the form of
$$T_6^0 = \begin{bmatrix} \bar{x}_6 & \bar{y}_6 & \bar{z}_6 & \bar{p}_6 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (3.14)$$

Where $\bar{x}_6$, $\bar{y}_6$ and $\bar{z}_6$ are $[3x1]$ unit vectors along the principle axes of the end-effectors coordinate frame $i$, see Fig. 3.29. Position vector $\bar{p}_6$ describes the hand about joint A1 (shoulder). The arm can be viewed in different frames. If we look at the arm in reference to the end-effector’s frame. The reverse transform is defined as $(T_6^0)^i$

$$(T_6^0)' = T_6^0 = (T_6^0)^{-1} = \begin{bmatrix} \bar{x}_6 & \bar{y}_6 & \bar{z}_6 & \bar{p}_6 \\ 0 & 0 & 0 & 1 \end{bmatrix}^{-1} \quad (3.15)$$

The following method is based on the work done by our partner Park et. al.[44]. The general link translation matrix $T_i^{i-1}$ relates the $i^{th}$ coordinate frame to the $(i-1)^{th}$ coordinate frame. In addition we can extend Equation 3.14 to

$$T_6^0 = \begin{bmatrix} \bar{x}_6 & \bar{y}_6 & \bar{z}_6 & \bar{p}_6 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} \bar{n} & \bar{s} & \bar{a} & \bar{p} \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (3.16)$$

Where $[\bar{n}, \bar{s}, \bar{a}, \bar{p}]$ represents the normal vector, the sliding vector, the approach vector and the position vector of the end effector respectively[46]. We can now state that

$$(T_6^0)' = T_6^0 = (T_6^0)^{-1} = \begin{bmatrix} \bar{x}_6 & \bar{y}_6 & \bar{z}_6 & \bar{p}_6 \\ 0 & 0 & 0 & 1 \end{bmatrix}^{-1} = \begin{bmatrix} \bar{n}' & \bar{s}' & \bar{a}' & \bar{p}' \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (3.17)$$

We can now use the reverse method to solve for the joint angles as in [46] and derived in the tech report[47]. The first three lower joint angles of $A_4$, $A_5$ and $A_6$ are solved for. Subsequently the upper joint angles of $A_1$, $A_2$ and $A_3$ are solved.
Using inverse transform methods [48] we can modify Equation 3.11 to

\[ T_0^6 = (T_0^6)^{-1} = \prod_{i=6}^{1} T_i^{i-1} = T_6^5 T_4^3 T_3^2 T_2^1 T_1^0 \]  

(3.18)

Then we equate Equation 3.16 to Equation 3.18

\[ T_6^5 T_4^3 T_3^2 T_2^1 T_1^0 = \begin{bmatrix} \bar{a}' & \bar{s}' & \bar{a}' & \bar{p}' \\ 0 & 0 & 1 \end{bmatrix} \]  

(3.19)

Then move \( T_6^5 \) to the other side of the equation

\[ T_4^3 T_2^1 T_1^0 = T_6^5 \begin{bmatrix} \bar{a}' & \bar{s}' & \bar{a}' & \bar{p}' \\ 0 & 0 & 1 \end{bmatrix} \]  

(3.20)

For simplicity we will represent Equation 3.20 as \( G_L \) and \( G_R \) standing for right and left side.

\[ G_L = T_5^6 \begin{bmatrix} \bar{a}' & \bar{s}' & \bar{a}' & \bar{p}' \\ 0 & 0 & 1 \end{bmatrix} \]  

(3.21)

\[ G_R = T_5^6 \begin{bmatrix} \bar{a}' & \bar{s}' & \bar{a}' & \bar{p}' \\ 0 & 0 & 1 \end{bmatrix} \]  

(3.22)

Expanding gives us

\[ G_L = \begin{bmatrix} g_{11} & g_{12} & g_{13} & \cos(\theta_6)(p_x' + l_{A4}) - \sin(\theta_6)p_y' \\ g_{21} & g_{22} & g_{23} & \sin(\theta_6)(p_x' + l_{A4}) - \cos(\theta_6)p_y' \\ g_{31} & g_{32} & g_{33} & p_z' \\ 0 & 0 & 0 & 1 \end{bmatrix} \]  

(3.23)

and
\[ G_R = \begin{bmatrix} g_{11} & g_{12} & g_{13} & \sin(\theta_4)\cos(\theta_5)l_{A_2} \\ g_{21} & g_{22} & g_{23} & -\cos(\theta_6)l_{A_2} - l_{A_3} \\ g_{31} & g_{32} & g_{33} & \sin(\theta_4)\sin(\theta_5)l_{A_2} \\ 0 & 0 & 0 & 1 \end{bmatrix} \] (3.24)

We can then equate elements (1, 4), (2, 4) and (3, 4) of \( G_L \) and \( G_R \). This gives us

\[ \cos(\theta_6)(p'_x + l_{A_4}) - \sin(\theta_6)p'_y = \sin(\theta_4)\cos(\theta_5)l_{A_2} \] (3.25)

\[ \sin(\theta_6)(p'_x + l_{A_4}) - \cos(\theta_6)p'_y = -\cos(\theta_6)l_{A_2} - l_{A_3} \] (3.26)

\[ p'_z = \sin(\theta_4)\sin(\theta_5)l_{A_2} \] (3.27)

Based on the desired task space location we let

\[ p'_x + l_{A_4} = r \cdot \cos(\phi) \] (3.28)

and

\[ p'_y = r \cdot \sin(\phi) \] (3.29)

where

\[ r = \sqrt{(p'_x + l_{A_4})^2 + (p'_y)^2} \] (3.30)

and

\[ \phi = \tan^{-1}(p'_y, p'_x + l_{A_4}) \] (3.31)
Note: $\text{atan2}()$ represents the the $\text{atan}$ method that gathers the information of the signs of the inputs in order to put the returned value in the appropriate quadrant.

Combining Equation (3.25), (3.26) and (3.27) with Equation (3.28) and (3.29) we get

$$r \cdot \cos(\theta_6 + \phi) = \sin(\theta_4)\cos(\theta_5)l_{A_2}$$  
(3.32)

$$r \cdot \sin(\theta_6 + \phi) = -\cos(\theta_4)l_{A_2} - l_{A_3}$$  
(3.33)

$$p_z' = \sin(\theta_4)\sin(\theta_5)l_{A_2}$$  
(3.34)

When we combine above with Equation (3.30) and (3.31) and obtain

$$\theta_4 = \text{atan2} \left( \pm \sqrt{1 - \cos(\theta_4)^2}, \cos(\theta_4) \right)$$  
(3.35)

where

$$\cos(\theta_4) = \frac{(p_x' + l_{A_4})^2 + p_y'^2 + p_z'^2 - l_{A_2}^2 - l_{A_3}^2}{2l_{A_2}l_{A_3}}$$  
(3.36)

Using Equation 3.34 we can get $\theta_5$

$$\theta_5 = \text{atan2}(\sin(\theta_5), \pm \sqrt{1 - \sin(\theta_5)^2})$$  
(3.37)

where

$$\sin(\theta_5) = \frac{p_z'}{\sin(\theta_4)l_{A_2}}$$  
(3.38)

We can then solve for $\theta_6$ by dividing Equation 3.33 by Equation 3.32.
\[
\frac{r \cdot \sin(\theta_6 + \phi)}{r \cdot \cos(\theta_6 + \phi)} = \tan(\theta_6 + \phi) = \frac{-\cos(\theta_4)l_{A_2} - l_{A_3}}{\sin(\theta_4)\cos(\theta_5)l_{A_2}} \tag{3.39}
\]

\[
\theta_6 = \text{atan2}(-\cos(\theta_4)l_{A_2} + l_{A_3}, \sin(\theta_4)\cos(\theta_5)l_{A_2}) - \phi \tag{3.40}
\]

Now that we have \(\theta_4, \theta_5\) and \(\theta_6\) we reconstruct \(G\) in reference to joint \(A_1, A_2\) and \(A_3\). We will call this \(G^*_L\). Like \(G\) we will have a right \((G^*_R)\) and left \((G^*_L)\) of \(G\):

\[
G^*_L = \begin{bmatrix}
     g^*_{11} & g^*_{12} & g^*_{13} & g^*_{14} \\
     g^*_{21} & g^*_{22} & g^*_{23} & g^*_{24} \\
     g^*_{31} & g^*_{32} & g^*_{33} & g^*_{34} \\
     0 & 0 & 0 & 1
\end{bmatrix}
\]

\[
G^*_R = \begin{bmatrix}
     \cos(\theta_1)\cos(\theta_2)\cos(\theta_3) - \sin(\theta_1)\sin(\theta_3) & \cos(\theta_1)\sin(\theta_3) + \sin(\theta_1)\cos(\theta_2)\cos(\theta_3) & \sin(\theta_2)\cos(\theta_3) & 0 \\
     -\cos(\theta_1)\sin(\theta_2) & -\sin(\theta_1)\sin(\theta_3) & \cos(\theta_2) & l_{A_2} \\
     \sin(\theta_1)\cos(\theta_3) + \cos(\theta_1)\cos(\theta_2)\sin(\theta_3) & \sin(\theta_1)\cos(\theta_2)\sin(\theta_3) - \cos(\theta_1)\cos(\theta_3) & \sin(\theta_2)\sin(\theta_3) & 0 \\
     0 & 0 & 0 & 1
\end{bmatrix}
\]

as before we can compare the elements of \(G^*_L\) and \(G^*_R\). Specifically compare element \((2, 3)\). We then get

\[
\cos(\theta_2) = \frac{\alpha^*_z \sin(\theta_4)\sin(\theta_5) - \alpha^*_y (\cos(\theta_4)\cos(\theta_6) + \sin(\theta_4)\cos(\theta_5)\sin(\theta_6))}{\sqrt{1 - \cos(\theta_2)^2}, \cos(\theta_2)} \tag{3.43}
\]

\[
\theta_2 = \text{atan2}(\pm \sqrt{1 - \cos(\theta_2)^2}, \cos(\theta_2)) \tag{3.44}
\]

If we take elements \((1, 3)\) and \((3, 3)\) of \(G^*_L\) with those of \(G^*_R\) we get
By dividing these two equations we can get $\theta_1$

$$\theta_2 = \text{atan2}(g_{33}^*, g_{13}^*)$$  \hfill (3.46)$$

and thus

$$IF : \sin(\theta_2) < 0 THEN : \theta_1 = \theta_1 + \pi$$  \hfill (3.47)$$

Fig. 3.31 shows the example of using Hubo-Ach to move the right end-effector to the desired work space coordinates using the IK method described in this section.

Video: http://danlofaro.com/phd/ik/#HuboTwoArmIk

Figure 3.31: Hubo preforming 6-DOF IK in real-time using method discussed in Section 6.0.4
3.8 Verification: Door Opening

Section 3.3, 3.6.1, and 3.6 verified the functionality of Hubo-Ach under different circumstances.

Zucker et. al. [12] independently validates Hubo-Ach through their work in *Continuous Trajectory Optimization for Autonomous Humanoid Door Opening*. Fig. 3.32 shows Zucker’s work.

In conclusion, Hubo-Ach is validated as being a useful unified algorithmic framework for complex systems and humanoid robots by peers. Shown to have consistent system performance in Section 3.3. It is verified via implementation of full body
kinematic examples in Section 3.6.1 and 3.7.

This section gives the prerequisites for the Hubo-Ach system, shows the user how to install/un-install the system, and how to use the built in tools. Programming examples in C/C++ and Python are also given.

4.1 Prerequisites

The following items are needed to run Hubo-Ach on a Hubo:

- Hubo2+ or OpenHubo (Virtual Hubo)
- SocketCAN compatible CAN card
- Debian based linux install - tested with Ubuntu 12.04 LTS
- Ach IPC installed

4.2 Installation

4.2.1 From Hubo-Ach Dep (Recommended)

Updates to latest release:

```
$h ub o - a c h u p d a t e
```

Updates to latest develop:

```
$h ubo - a c h u p d a t e d e v e l o p
```
From Repo:

(1) Add one of the two lines to `/etc/apt/sources.list`

```text
deb http://www.repo.danlofaro.com/release precise main # Development
deb http://www.drc-hubo.com/release precise main # Stable Release
```

(2) Install via apt-get:

```bash
$ sudo apt-get update
$ sudo apt-get install hubo-ach hubo-dev
```

or

```bash
$ hubo-ach update apt-get
```

### 4.2.2 From Source

Install from source

Download the source and install

```bash
$ git clone https://github.com/hubo/hubo-ach.git
$ cd hubo-ach
$ autoreconf -i
$ ./hubo-ach-install.sh
```

Uninstall/Clean Hubo-Ach

Removed all Hubo-Ach version from deb, apt-get and source
4.3 Usage

Starting Hubo-Ach will automatically start the interface between hubo and the user called hubo-console

4.3.1 Hubo-Ach Main Interface

Available commands

$ hubo-ach

Start Hubo-Ach on Hubo

$ hubo-ach start

Start Hubo-Ach on OpenHubo (Virtual Hubo)

$ hubo-ach virtual

4.3.2 Update Hubo-Ach

Updates to latest release:

$ hubo-ach update

Updates to latest develop:
$ hubo-ach update develop

Updates via apt-get

Dependent on your apt-get entry in /etc/apt/source.list:

<table>
<thead>

$ hubo-ach update apt-get

Remove Hubo-Ach

Removed all installed versions of Hubo-Ach including from source.

$ hubo-ach clean

Start Hubo-Ach Console

$ hubo-ach console

Start Hubo-Ach Read Tool

$ hubo-ach read

Start Remote Connection

Connection is made from the client to the server where the robot is the server. The robot’s has an IP address of xxx.xxx.xxx.xxx and is the hubo-ach computer. Note: you have to have to enable the network daemon via the process described here: http://golems.github.com/ach/manual/#AEN399
$ hubo-ach remote xxx-xxx-xxx-xxx

Kill Remote Connection

$ hubo-ach remote kill

Make Ach Channels

Creates Ach channels for Hubo-Ach without starting the Hubo-Ach Daemon

$ hubo-ach make

4.3.3 Hubo-Console

Hubo-Console is a basic user interface between the Hubo and the user. It allows you to do the following:

- Home a single joint
- Home all joints at once
- Reset joint errors
- Initialize sensors

Note: In all examples below XXX stands for the standard joint naming i.e. RHP, RHR, LSP, LSR, etc. Hubo-Console will start automatically when you type:

$ hubo-ach start

If Hubo-Ach is already started you can start hubo-console by:
$ hubo-ach console

Once Hubo-Console has started you will be able to:

**Home Joint XXX**

This will make the joint move to find the limit switch then goto its predefined offset. The reference will be set to zero.

```
>> hubo-ach: home XXX
```

**Home All Joints**

This will make all of the joints move to find their respective limit switches and goto their predefined offsets at the same. The reference to all joints are set to zero. Note: All joints will move at the same time. The robot should not be on the ground when this is done.

```
>> hubo-ach: homeAll
```

**Initialize All Sensors**

This will initialize all sensors including the IMU and FT sensors. The robot should be off the ground and not moving.

```
>> hubo-ach: iniSensors
```

**Initialize All Joints**

This will initialize all joints. Note: They will maintain the current control mode. If they were inactive they will be active and able to read back encoder values at this point.
>> hubo-ach: initializeAll

Clear Errors on Joint XXX

This will clear the following errors on joint XXX.

- Big Error
- Encoder Error
- Homing Error

>> hubo-ach: reset XXX

Clear Errors on All Joints

This is the same as reset but will clear errors on all active joints

>> hubo-ach: resetAll

Joint XXX goto position

Commands joint XXX to goto position YYY (in radians)

>> hubo-ach: goto XXX YYY

Turn on/off Joint XXX Controller

This will turn on or off the controller for joint XXX. Note: Y represents the desired state

- 1 = on
- 0 = off
>> hubo-ach: ctrl XXX Y

**Turn on/off All Joint Controllers**

This is the same as Turn on/off Joint XXX Controller but it applies to all joints:

>> hubo-ach: ctrlAll Y

**Check Status of Joint XXX**

Check the status of joint XXX

>> hubo-ach: status XXX

### 4.3.4 Hubo-Read

Hubo-Read is a simple tool that prints out the reference and state channels to the console. You can start Hubo-Read in one of two ways:

**Method 1**

$ hubo-ach read

**Method 2**

Note: the sudo is needed because it uses RT permissions for the loop.

$ sudo hubo-read

What you will see

4.4 Simulator

This section shows how to run a Hubo simulator in conjunction with Hubo-Ach. Note: The simulator is a full 3D simulator and is recommended to run on a computer other than the Hubo body computer. It will work on it but it will be slow.

4.4.1 Prerequisites

OpenHubo

To install OpenHubo follow the directions here:

- http://dasl.mem.drexel.edu/drcwiki/index.php/OpenHubo_Introduction

Assuming you have all of the prerequisites you can simply do the following to install OpenHubo:

```
$ git clone --recursive https://github.com/hubo/openHubo.git
$ cd openHubo
$ ./setup
```

4.4.2 Using the Simulator

Once OpenHubo is installed you can run the simulator. The simulator at the moment is restricted to kinematic output. Dynamics do not run in real-time.
This simulator creates two models overlaid on each-other. The green model is the commanded reference sent to the actuator. The solid model is the actual position as read from the encoders. Note: if the robot is not on this will stay zero but the green reference will move. To run the simulator:

**With No Physics (fast):**

Starts OpenHubo running with no physics. This is good for watching what the robot is doing live or to preview trajectories.

```
$ hubo-ach sim openhubo nophysics
```

**With Physics:**

Starts OpenHubo running with physics. This runs at about 35% real time (on an i7 processor). The simulator and hubo-ach are synced via triggering from newly received messaged on the following Ach channels:

- HUBO_CHAN_VIRTUAL_TO_SIM_NAME
- HUBO_CHAN_VIRTUAL_FROM_SIM_NAME

Please note that the state channel will have simulation time NOT real time.

```
$ hubo-ach sim openhubo physics
```

### 4.4.3 Run Visualizer

You can use OpenHubo as a real-time (live) visualizer of our state data on your computer in which you login to the Hubo from. This will show the OpenHubo model using no physics. The green shows what the joints are commanded to and the grey
show where the joints are. This will run with little to no lag/latency on an i5 or i7 processor. In order to do this start hubo-ach normally on the hubo:

```
(hubo@xxx.xxx.xxx.xxx) $ hubo-ach start
```

On your control computer (not the hubo) start the simulator with remote

```
(i5 or i7) $ hubo-ach sim openhubo nophysics remote xxx.xxx.xxx.xxx
```

### 4.5 Programming

This section will show quick examples of how to program using Hubo-Ach in C/C++ and Python

#### 4.5.1 C/C++

The C/C++ Example is available below. This is bare bones for you to:

- Get the latest feed-back (state) channel information.

- Set the feed-forward (reference) information.

**C/C++ Example (hubo-simple-demo.c)**

```c
/* Standard Stuff */
#include <string.h>
#include <stdio.h>

/* Required Hubo Headers */
#include <hubo.h>

/* For Ach IPC */
#include <errno.h>
#include <fcntl.h>
```
```c
#include <assert.h>
#include <unistd.h>
#include <pthread.h>
#include <ctype.h>
#include <stdbool.h>
#include <math.h>
#include <inttypes.h>
#include "ach.h"

/* Ach Channel IDs */
ach_channel_t chan_hubo_ref; // Feed-Forward (Reference)
ach_channel_t chan_hubo_state; // Feed-Back (State)

int main(int argc, char **argv) {

    /* Open Ach Channel */
    int r = ach_open(&chan_hubo_ref, HUBO_CHAN_REF_NAME , NULL);
    assert( ACH_OK == r );
    r = ach_open(&chan_hubo_state, HUBO_CHAN_STATE_NAME , NULL);
    assert( ACH_OK == r );

    /* Create initial structures to read and write from */
    struct hubo_ref H_ref;
    struct hubo_state H_state;
    memset( &H_ref, 0, sizeof(H_ref));
    memset( &H_state, 0, sizeof(H_state));
```
/ for size check */
size_t fs;

/* Get the current feed-forward (state) */
r=ach_get(&chan_hubo_state, &H_state, sizeof(H_state), &fs, NULL, ACH_O_LAST);
if(ACH_OK != r) {
    assert( sizeof(H_state) == fs );
}

/* Set Left Elbow Bend (LEB) and Right Shoulder Pitch (RSP) */
/* to -0.2 rad and 0.1 rad respectively */
H_ref.ref[LEB] = -0.2;
H_ref.ref[RSP] = 0.1;

/* Print out the actual position of the LEB */
double posLEB = H_state.joint[LEB].pos;
printf("Joint = %f\r\n", posLEB);

/* Print out the Left foot torque in X */
double mxLeftFT = H_state.ft[HUBO_FT_L_FOOT].m_x;
printf("Mx = %f\r\n", mxLeftFT);

/* Write to the feed-forward channel */
ach_put( &chan_hubo_ref, &H_ref, sizeof(H_ref));

}

Where the default MakeFile is:

C/C++ Default MakeFile
default: all

CFLAGS := -I./include -g --std=gnu99
CC := gcc

BINARIES := hubo-simple-demo
all : $(BINARIES)

LIBS := -lach

hubo-simple-demo: src/hubo-simple-demo.o
gcc -o $@ $< $(LIBS)

%.o: %.c
$(CC) $(CFLAGS) -o $@ -c $<

clean:
rm -f $(BINARIES) src/*.o

Run the example

The C/C++ example uses the MakeFile seen in Section 4.5.1. You just need to make and run

$ make clean
$ make
$ ./hubo-simple-demo

4.5.2 Python

The Python Example is available below. This is bare bones for you to:
• Get the latest feed-back (state) channel information

• Set the feed-forward (reference) information

Please note that:

• Must use Hubo-Ach ñ = 0.0.20130319

• The Ach python bindings must be installed. You can install via PIP (see below)

$ sudo apt-get install python-pip
$ sudo pip install http://code.golems.org/src/ach/py_ach-latest.tar.gz

Python Example (hubo-simple-demo.py)

```python
#!/usr/bin/env python
# /* -*- indent-tabs-mode:t; tab-width: 8; c-basic-offset: 8 -*- */

import hubo_ach as ha
import ach
import sys
import time
from ctypes import *

# Open Hubo-Ach feed-forward and feed-back (reference and state) channels
s = ach.Channel(ha.HUBO_CHAN_STATE_NAME)
r = ach.Channel(ha.HUBO_CHAN_REF_NAME)
s.flush()
r.flush()

# feed-forward will now be refered to as "state"
state = ha.HUBO_STATE()

# feed-back will now be refered to as "ref"
```
ref = ha.HUBO_REF()

# Get the current feed-forward (state)
[statuss, framesizes] = s.get(state, wait=False, last=False)

# Set Left Elbow Bend (LEB) and Right Shoulder Pitch (RSP)
# to -0.2 rad and 0.1 rad respectively
ref.ref[ha.LEB] = -0.2
ref.ref[ha.RSP] = 0.1

# Print out the actual position of the LEB
print "Joint = ", state.joint[ha.LEB].pos

# Print out the Left foot torque in X
print "Mx = ", state.ft[ha.HUBO_FT_L_FOOT].m_x

# Write to the feed-forward channel
r.put(ref)

# Close the connection to the channels
r.close()
s.close()

Run the example

The python example can be run via:

$ python ./hubo-simple-demo.py
4.6 Connecting a Simulator to Hubo-Ach

This is a brief example of how to connect a simulator to Hubo-Ach. In this example we will be running Hubo-Ach in simtime mode. This makes Hubo-Ach wait for a trigger from the simulator. This trigger tells Hubo-Ach that it has updated the state data with the simulated state data. Hubo-Ach will then run and send a trigger to the simulator telling it that it can do its next calculation.

Hubo-Ach is simulator agnostic. The examples is given in this section uses the OpenHubo simulator described in Section 4.6.1

4.6.1 Simulator

The simulator used for Hubo-Ach is the OpenHubo. OpenHubo is an open-source kinematic and dynamic simulator for the the Hubo2 and Hubo2+ series robots. It was developed by the Drexel Autonomous Systems Lab and runs using the open-source robot simulation environment OpenRAVE[16]. Fig. 4.1 shows the OpenHubo shell model and collision model.

The masses and lengths are of the OpenHubo model are all based off of the CAD model. The shell model includes an external skin based off of the CAD model of the Hubo’s shell. This model is high polygon count and thus tends to require more processing time to detect collisions. The collision model is constructed out of primitives in order to decrease the complexity of the model and decrease required processing time. The collision model is a representation of the shell model. It does not precisely fit the contours but through experimentation and use has been calibrated to be a good representation of the Hubo’s outer shell.

Fig 4.2 shows the diagram of how the OpenHubo simulator is connected to Hubo-Ach. No changes to previous controllers are required for them to work with the simulator. Just as before the desired reference $\theta_d$ being filtered before applied to
Figure 4.1: OpenHubo model of the Hubo2 humanoid robot developed by the Drexel Autonomous Systems Lab and runs using the open-source robot simulation environment OpenRAVE[16]. (Left) Shell Model - High polygon count. (Right) Collision model - Made with primitives.
Hubo via Hubo-Ach. $\theta_d$ is sent through a filter that reduces the \textit{jerk} on the actuator then the new reference $\theta_r$ is set on the \textbf{FeedForward} channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle. At this point the \textit{to simulator} trigger, $\Gamma_{ts}$, is set high and the OpenHubo simulator reads $\theta_c$. The simulator waits until Hubo-Ach is ready until it starts its next set of cycles. The reference is set within OpenHubo and solved with a simulation period of $T_{sim}$. The simulation period $T_{sim}$ must be an integer deviser of the robot real-time period $T_r$. In this case

$$T_r = 0.005 \text{ s} \quad (4.1)$$

$$T_{sim} = \frac{T_r}{n} \quad (4.2)$$

Once the simulator has gone through $n$ cycles the current state, $H_{state}$ is placed on the Hubo-Ach \textbf{FeedForward} channel and the ready trigger $\Gamma_{fs}$ is raised. Hubo-Ach is waiting for the rising edge of the \textit{from simulator} trigger, $\Gamma_{fs}$, to continue on to the next cycle.

The external controllers do not know weather Hubo-Ach is running in \textit{simulation} or \textit{real-time} mode. In order to ensure a Hubo-Ach controller stays what ever timing method is being used the controller can do any of the following:

- Wait for the $\Gamma_{fs}$ trigger
- Wait for a new $H_{pstate}$ to be updated
- Watch the time listed within $H_{state}$

If the given task does not require physics or feedback from $H_{state}$ then you can run in \textit{no physics} mode. \textit{No physics} mode only gives collisions, joint angles and ideal
Figure 4.2: Diagram of how the OpenHubo simulator is connected to Hubo-Ach. No changes to previous controllers are required for them to work with the simulator. Just as before the desired reference $\theta_d$ being filtered before applied to Hubo via Hubo-Ach. $\theta_d$ is sent through a filter that reduces the jerk on the actuator then the new reference $\theta_r$ is set on the FeedForward channel, Hubo-Ach reads it then commands Hubo at the rising edge of the next cycle. At this point $\Gamma_{ts}$ is set high and the OpenHubo simulator reads $\theta_c$. The reference is set within OpenHubo and solved with a simulation period of $T_{sim}$. Once the state, $H_{state}$ has been determined it is placed on the Hubo-Ach FeedForward channel and the ready trigger $\Gamma_{fs}$ is raised. Hubo-Ach is waiting for the rising edge of $\Gamma_{fs}$ to continue on to the next cycle.

Table 4.1: OpenHubo simulator sim-time and real-time comparison chart. Shows the maximum percent real-time the OpenHubo simulator is capable of preforming at where 100% is real-time. All tests were preformed on an Intel i7 running at 2.8Ghz with 18Gb of RAM.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Timing</th>
<th>Maximum Percent Real-Time (%)</th>
</tr>
</thead>
<tbody>

<td>362%</td>
</tr>
</tbody>
</table>

feedback from the sensors. In addition no physics is capable of running much faster then real-time if needed.

Fig. 4.3 shows the capability of Hubo-Ach to run in both sim-time and real-time modes. This is the same statically stable trajectory as seen in Section 5.1.1
4.6.2 Setup

Step 1: Start Hubo-Ach in SimTime mode

This mode makes hubo-ach wait for a trigger from the simulator. This trigger is when the HUBO_CHAN_VIRTUAL_FROM_SIM_NAME channel has been updated.

$ hubo-ach sim

Step 2: Run your simulator

Run your simulator. The simulator must do the following in this order

(Sudo Code)

Open all needed Channels

Write to HUBO_CHAN_VIRTUAL_FROM_SIM_NAME channel

Loop:

Wait for HUBO_CHAN_VIRTUAL_TO_SIM_NAME channel update

Set feed forward data from H_state.joint[jnt].ref to your simulator

Do simulation

Populate state data to H_state struct

H_state.joint[jnt].pos
Step 3: Run a Hubo-Ach controller of your choosing

You can now run any hubo-ach controller with no modification required. Note: If you want to take into account the simtime then it must either:

- Watch the state time `H_state.time`
- Wait for the following triggers:
  - `HUBO_CHAN_VIRTUAL_FROM_SIM_NAME`
  - `HUBO_CHAN_VIRTUAL_TO_SIM_NAME`

4.6.3 C/C++ Simulation Example

This example code shows the basics of connecting to Hubo-Ach using simtime mode with triggering. The example can be found on the hubo group on github in the example/simtime branch:

```bash
$ git clone https://github.com/hubo/hubo-simple-demo.git
$ cd hubo-simple-demo
$ git checkout example/simtime
```

C/C++ Simulation Example (hubo-simple-demo.c) - simtime branch

```c
/* Standard Stuff */
#include <string.h>
#include <stdio.h>
```
/* Required Hubo Headers */
#include <hubo.h>

/* For Ach IPC */
#include <errno.h>
#include <fcntl.h>
#include <assert.h>
#include <unistd.h>
#include <pthread.h>
#include <ctype.h>
#include <stdbool.h>
#include <math.h>
#include <inttypes.h>
#include "ach.h"

/* Ach Channel IDs */

ach_channel_t chan_hubo_ref;     // Feed-Forward (Reference)
ach_channel_t chan_hubo_state;   // Feed-Back (State)
ach_channel_t chan_hubo_to_sim;  // To Sim
ach_channel_t chan_hubo_from_sim; // From Sim

int main(int argc, char **argv) {

    int i = 0;

    /* Open Ach Channel */
    int r = ach_open(&chan_hubo_ref, HUBO_CHAN_REF_NAME , NULL);
    assert( ACH_OK == r );

    r = ach_open(&chan_hubo_state, HUBO_CHAN_STATE_NAME , NULL);
    assert( ACH_OK == r );

Run the example

The simulation example uses the same make file from the hubo-simple-demo in Section 4.5.1. You just need to make and run

```
$ make clean
$ make
$ ./hubo-simple-demo
```
5. Experiment

This section gives examples of the Hubo-Ach system being used on the physical and simulated systems. Examples include: a walking controller implementation on the physical robot and in simulation; visual servoing while walking using the physical robot; and active damping implementation using the physical robot.

5.1 Walking

This section shows examples of how Hubo-Ach was used for stable walking. Examples are given using:

- Hubo2+ (Physical Robot)
- OpenHubo (Simulator)
- RobotSim Hubo (Simulator)

Section 5.1.1 shows how the open-loop walking trajectory is created.

Section 5.1.2 shows how the open loop walking trajectory is run in sim-time on OpenHubo using Hubo-Ach. Section 5.1.3 shows how the open loop walking trajectory is run in sim-time on RobotSim using Hubo-Ach. Section 5.1.4 shows the same walking trajectory running on the real Hubo hardware in real-time using Hubo-Ach. It also shows the difference between running in sim-time and real-time. Section I shows the result of a five day hack-a-thon using Hubo-Ach to add dynamic walking capability.
5.1.1 Walking Pattern Generation

The walking pattern demonstrated in this section is generated based on the work of Park et. al.[49] A walking pattern is the way in which a legged robot, in this case two legged, moves its joints to create a walking gate while maintaining stability. The walking pattern consists of two major phases:

- Single Support Phase (SSP)
- Double Support Phase (DSP)

**Single support phase** is when one foot is on the ground. This phase is when one leg moves from one stepping position to the other. The ZMP must remain above the planted foot to guarantee stability.

**Double support phase** is when both feet are planted on the ground. When in this phase the ZMP moves from above one foot to the other along the stable area as seen in Fig. G.1.

Fig 5.1 and 5.2 shows the walking pattern phases on a Hubo model in the $x$ and $y$ direction respectively. In these figures $A_R$ and $A_L$ defines the left and right ankles respectively. $t_1$ is the time of the starting of the step, $t_2$ defines the landing of the stepping foot. $t_0$ defines time when the stepping foot is at peak step height. $P$ defines the hip location. $\tilde{x}$ defines the walking velocity. $\tilde{y}$ defines the body sway velocity. The middle diagram depicts the SSP and the left and right diagrams show the DSP.

The walking patterns are generated creating a joint space trajectory with a period $T$ of 0.005 sec. The patterns keep the ZMP criteria described in Section G. These walking patterns are used to test the simulated robots and the physical robots. Fig. 5.3 shows the joint space walking pattern verses time.
4) Small number of factors which are needed to be tuned

Walking pattern is needed to be tuned to increase its performance, because the acceptability of the pattern itself can be validated by experiment. We want to tune the robot easily. We describe the position of the pelvis centre and the ankle in the viewpoint of sagittal and coronal plane in this paper.

**Figure 4 Coordinate description**

**A. Sagittal view (X-Direction)**

- $A$ is located on the front supporting foot during the other leg swings in $x$ direction. $t_1$ is the start time of swing from DSP (Double Support Phase) and $t_2$ is the end time of swing to the other DSP. We assumed that the pelvis center position is on the center of two ankles at $t_1$ and $t_2$. First, we generated the pelvis and the swing leg trajectory in this local coordinate frame $-x$, and implemented to the robot on the basis of $x$ frame by translating the coordinate frame.

Equation (1) shows the ankle position and (2) shows the pelvis centre position in the local coordinate frame.

\[
X_A(t) = \left( b + f \right) t - t_1 \sin \frac{\theta}{2} t - t_1 + b
\]

Equation (2) is a 3rd order polynomial interpolation curve. We need to have flexibility of the curve shape change by $a$ shown in (3), because it directly affects the shape of ZMP trajectory. The curve is generated by defining its boundary values at start and end of the single step as shown in (3). We normalized the time scale of (2) from 0 (= $t_1$) to 1 (= $t_2$) and we assumed that the speed of the pelvis centre is in proportion with its initial and final position of the swing ankle position. We can get the values of $a_i$ by the time scale normalization as shown (4).

**Figure 5.1: Hubo model diagram for ZMP walking in the $x$ direction (side view).** $b$ and $f$ are the step lengths for the left and the right foot. $A$ defines the ankle. $t_1$ is the time of the starting of the step, $t_2$ defines the landing of the stepping foot. $P$ defines the hip location. $\bar{x}$ defines the walking velocity. The middle diagram depicts the SSP and the left and right diagrams show the DSP.

**5.1.2 Walking Using OpenHubo Simulator and Hubo-Ach**

The walking pattern that was generated in Section 5.1.1 was then applied to the OpenHubo system described in Section 4.6.1 via the Hubo-Ach controller. The walking pattern was applied in sim-time with a period $T_{sim}$ of 0.005 sec. The block diagram of the system using OpenHubo in sim-time for a walking trajectory is shown in Fig. 5.7.

In Fig. 5.7 the OpenHubo simulator is connected to Hubo-Ach and is used to run the walking trajectory. The walking pattern generator ensures proper constraints on the velocity, acceleration and jerk and thus the filter seen in Fig. 4.2 is not desired. $\theta_r$ is set directly on the FeedForward channel thus each joint will have the response as seen in Fig. 3.16 for each commanded reference command at each time step. Hubo-Ach reads the FeedForward channel and commands Hubo at the rising edge of the next cycle. At this point $\Gamma_{ts}$ is set high and the OpenHubo simulator reads $\theta_c$. The reference is set within OpenHubo and solved with a simulation period of $T_{sim}$. Once The state, $H_{state}$ has been determined it is placed on the Hubo-Ach FeedForward
channel and the ready trigger $\Gamma_{fs}$ is raised. Hubo-Ach is waiting for the rising edge of $\Gamma_{fs}$ to continue on to the next cycle. In order to keep with the sim-time the Walking Pattern also waits for the rising edge of $\Gamma_{fs}$ to put the next desired reference on the FeedForward channel. Fig. 5.5 shows the Virtual Hubo successfully ZMP walking using OpenHubo and Hubo-Ach.

5.1.3 Walking Using RobotSim and Hubo-Ach

The walking pattern that was generated in Section 5.1.1 was then applied to the RobotSim dynamic simulator via the Hubo-Ach controller. RobotSim was developed by Professor Kris Hauser from Indiana University. The simulator was integrated into Hubo-Ach on April 24th, 2013 during a 12 hour Hack-A-Thon at Worchester Polytechnic Institute by Daniel M. Lofaro, Jingru Luo and Professor Kris Hauser[50]. The walking pattern was applied in sim-time with a period $T_{sim}$ of 0.005 sec. The
Figure 5.3: Joint space walking pattern. The trajectory sampling period $T$ is 0.005 sec. Forward step length is 0.2 m, sway velocity $\tilde{y}$ is 0.062 m/sec, and step period is 0.8 sec.

block diagram of the system using RobotSim in sim-time for a walking trajectory is shown in Fig. 5.8.

In Fig. 5.8 the RobotSim simulator is connected to Hubo-Ach and is used to run the walking trajectory. The walking pattern generator ensures proper constraints on the velocity, acceleration and jerk and thus the filter seen in Fig. 4.2 is not desired. $\theta_r$ is set directly on the FeedForward channel thus each joint will have the response as seen in Fig. 3.16 for each commanded reference command at each time step. Hubo-Ach reads the FeedForward channel and commands Hubo at the rising edge of the next cycle. At this point $\Gamma_{ts}$ is set high and the RobotSim simulator reads $\theta_c$. The reference is set within RobotSim and solved with a simulation period of $T_{sim}$. Once The state, $H_{state}$ has been determined it is placed on the Hubo-Ach FeedForward
Figure 5.4: Diagram of how the OpenHubo simulator is connected to Hubo-Ach and is used to run a walking trajectory. The walking pattern generator ensures proper constraints on the velocity, acceleration and jerk and thus the filter seen in Fig. 4.2 is not desired. $\theta_r$ is set directly on the FeedForward channel thus each joint will have the response as seen in Fig. 3.16 for each commanded reference command at each time step. Hubo-Ach reads the FeedForward channel and commands Hubo at the rising edge of the next cycle. At this point $\Gamma_{ts}$ is set high and the OpenHubo simulator reads $\theta_c$. The reference is set within OpenHubo and solved with a simulation period of $T_{sim}$. Once the state, $H_{state}$ has been determined it is placed on the Hubo-Ach FeedForward channel and the ready trigger $\Gamma_{fs}$ is raised. Hubo-Ach is waiting for the rising edge of $\Gamma_{fs}$ to continue on to the next cycle. In order to keep with the sim-time the Walking Pattern also waits for the rising edge of $\Gamma_{fs}$ to put the next desired reference on the FeedForward channel.

channel and the ready trigger $\Gamma_{fs}$ is raised. Hubo-Ach is waiting for the rising edge of $\Gamma_{fs}$ to continue on to the next cycle. In order to keep with the sim-time the Walking Pattern also waits for the rising edge of $\Gamma_{fs}$ to put the next desired reference on the FeedForward channel. Fig. 5.6 shows the Virtual Hubo successfully ZMP walking using RobotSim and Hubo-Ach.
5.1.4 Hubo Walking using Hubo-Ach

The walking pattern that was generated in Section 5.1.1 was then applied to the physical Hubo platform using the Hubo-Ach controller. The walking pattern was applied in real-time with a period $T_r$ of 0.005 sec. Unlike the simulated versions which run in sim-time the system is now running in real-time; thus it no longer needs to wait for an external trigger. The walking pattern trajectory is now posted to the FeedForward channel at an RT period of $T_r$. The walking pattern generator ensures proper constraints on the velocity, acceleration and jerk and thus the filter seen in Fig. 4.2 is not desired. Fig. 5.9 shows the block diagram of the walking pattern from Section 5.1.1 being run in real-time on the physical Hubo2+ platform. Fig. 5.10 shows the Hubo successfully ZMP walking using OpenHubo and Hubo-Ach. Fig. 5.11 shows the Hubo successfully ZMP walking in place using OpenHubo and Hubo-Ach.

5.2 Visual Serving Example

This section uses visual feedback using an RGB-D (Red Green Blue - Depth) camera and the walking trajectories given in Section 5.1. The goal of this experiment is to have the robot visually track an object, walk towards the object, and stop when it is within 0.2 m of it.
Figure 5.10: Hubo2+ performing ZMP walking using Hubo-Ach in real-time based on the walking pattern generated in Section 5.1.1.

Video: http://danlofaro.com/phd/walking/#WalkingHubo

Figure 5.11: Hubo2+ performing ZMP walking in place using Hubo-Ach in real-time based on the walking pattern generated in Section 5.1.1 with a forward velocity of 0.0 m/sec.

Video: http://danlofaro.com/phd/walking/#WalkingInPlaceHubo
5.2.1 Tracking Using Vision

Using a well-known HSV (Hue Saturation Value) tracking algorithm. HSV tracking was implemented via the use of built-in libraries in OpenCV[51]. The depth is found by averaging the distance data from the tracked location of the HSV color on the RGB-D device.

Fig. 5.12 shows the block diagram of the full system. The \((x, y, z)\) work space position of the object is found via HSV tracking. The rotation error \(\theta_e\) and distance of the object from the projection of the robot onto the ground \(X_e\) is sent to the walking planner. The walking planner decides if it has to turn or walk forwards. The robot will stop when it is within 0.2 m of the object and facing it within an error of \(\pm 0.02 \text{ rad}\). The walking planner is a state machine with the following characteristics:
$$f(\theta_e, X_e) = \begin{cases} 
\theta_e > 0.3 \text{ rad} & \text{THEN turn 0.3 rad} \\
\theta_e < -0.3 & \text{THEN turn -0.3 rad} \\
0.3 \text{ rad} > \theta_e > 0.02 \text{ rad} & \text{OR THEN turn } \theta_e \text{ rad} \\
-0.02 < \theta_e < -0.3 \text{ rad} & \\
-0.02 < \theta_e < 0.02 \text{ rad} & \text{AND THEN step forward 0.1 m} \\
X_e > 0.2 \text{ m} & \\
\text{else} & \text{THEN stop} 
\end{cases}$$ (5.1)

5.2.2 Visual servoing during full-body locomotion task

Hubo using Hubo-Ach to walk and track a blue box. The robot will walk towards the blue box until it is within $0.2 \text{ m}$ at which point it will stop. If the box moves, the robot will turn to track the box. It is tracking the box in work-space via an RGBD camera and the HSV tracking method described in Section 5.2.1. Section 5.1 describes the method used for the walking task. Fig. 5.14 shows the robot completing this task.

http://danlofaro.com/phd/tracking/#TrackingAndWalking

Figure 5.14: Hubo using Hubo-Ach to walk and track a blue box. The robot will walk towards the blue box until it is within $0.2 \text{ m}$ at which point it will stop. If the box moves, the robot will turn to track the box.

5.3 Active Damping

Using feedback from the force-torque sensors the Hubo-Ach controller adds compliance to the legs via active damping. Fig. 5.15 shows as the user pushes down on the robot the force is detected by the force-torque (FT) sensors. This then modifies the joint commands such that the center of mass (CoM) acts like there is an over-damped spring-damper system between it and mechanical ground.

Python Source Code for Active Damping using force-torque sensors
#!/usr/bin/env python
# /* -*- indent-tabs-mode:t; tab-width: 8; c-basic-offset: 8 -*- */
import hubo_ach as ha
import ach

# Close the connection to the channels
r.close()
s.close()

Figure 5.15: Using feedback from the force-torque sensors the Hubo-Ach controller adds compliance to the legs via active damping.
6. Conclusion

This work shows the successful creation of a *Unified Algorithmic Framework for High Degree of Freedom Complex Systems and Humanoid Robots*. It was shown that the Hubo-Ach system works as the unifying algorithmic framework for the three tier infrastructure described in Section 1.2. This means Hubo-Ach works with all three tiers including:

- Rapid Prototype (RP) phase with zero cost to entry (OpenHubo Platform Section 2.4.3)
- Test and Evaluation (T&E) phase with low cost to entry (Mini-Hubo Platform Section 2.4.2)
- Verify and Validate (V&V) phase with lease-time cost to entry (Hubo Platform Section 2.4.1)

The three tier infrastructure was used to enable the robot to throw a ball. This resulted in a unique algorithm for end-effector velocity control called Sparse Reachable Maps (SRM) (Section K.1). One end-effector velocity control method was used in a live throwing experiment at a baseball game (Section L.1). The challenges from this successful experiment was answered by the creation of the following controllers.

- **Challenge:** Aiming the throw: Answer: Visual serving while performing full body locomotive task (Section 5.2)
- **Challenge:** Safely landing when throwing: Answer: Active damping via force-torque feedback (Section 5.3)

The Hubo-Ach system was verified under many circumstances including:
• Real-time closed form inverse kinematic controller (Section 3.6)

• Full body locomotive task of turning a valve (Section 3.6.1)

• Full body locomotive task of walking (Section 5.1.2)

Hubo-Ach was independently validated by other researcher through the examples of:

• Door opening (Section 3.8)

• Dynamic walking (Appendix I)

A study/survey done on how well the Hubo-Ach system performs as a unifying algorithmic framework returned positive results (Section M). The result is the creation of a truly Unified Algorithmic Framework for High Degree of Freedom Complex Systems and Humanoid Robots.

6.1 Future Work

Future work includes applying the framework to the DRC-Hubo for the DARPA Robot Challenge. In addition an over arching goal is to implement Hubo-Ach on other high DOF robots such as HRP-2, Baxter etc. thus creating a truly Unified Algorithmic Framework for High Degree of Freedom Complex Systems and Humanoid Robots. This will allow for a greater ease of controller sharing and increase positive research output.

Appendix E. Increasing Degrees of Freedom

Degree of freedom (DOF) is the number of independent parameters that can be varied in a mechanical system. Simply put the DOF of a robot is the number independent joints the robot contains. In modern robot implementation each joint is controlled by an actuator. Each actuator is controlled by the controller. The more DOF the more complex the controller.

In the early 1930s simple two DOF robots were used by the soviets as explosive devices[61]. These robots were remote control and had no mind of their own. In 1948 William Grey Walter created the first autonomous robots Tortoise Elmer and Elise[56]. Each of these simple two DOF robots were programmed in hardware to go towards a light source. This was referred to as BEAM Robot (Biology, Electronics, Aesthetics, and Mechanics) because of how the hardware configuration mimicked the electrical connections in an animals brain. In later years robots were being programmed in software to help create the first industrial robot UNIMATE which was a 6 DOF arm created by General Motors in 1954[62]. Lunokhod 2, a soviet lunar rover which landed on the moon in 1973, was equipped with a laser ranging system and a TV camera. It contained 11 DOF and had automated systems onboard, however it was primarily a remote controlled vehicle. By 1986 Rodney Brooks, co-founder and CTO of iRobot Corp., created Allen, a 18 DOF humanoid robot. The complexity and number of DOF keeps on increasing. By 1997 Honda completed the 28 DOF P3, a early version of what will become ASIMO [58]. Today with the
presents of HUBO, ASMO and HRP-4C it is common place for a robot to contain upwards of 40 DOF. A study done on 180 robots from the early 20th century to the present projects that by the year 2020 it will be as common to have a 70 DOF robot as it is to have a 40 DOF robot in 2013, see Fig. E.1. *The trend of increasing DOF in robots makes creating a control structure for these systems timely.*

These high DOF robots require complex control systems and strategies.

Creating controllers for these high degree of freedom complex systems is essential for development of the next generation of robots. Due to the inherent complexity and often high expense of these systems, controllers must be able to be tested and verified.

![Degrees of Freedom of Robots from 1929 to Present](image)

Figure E.1: Number of degrees of freedom for robots form 1929 to the present.
Appendix F. Inspiration: DARPA Robotics Challenge

In October 2012 DASL received officially become a Track-A team for the DRC. The team is now called DRC-Hubo. In December 2012 Hubo-Ach was chosen as the primary controller for the DRC-Hubo team. This would be another source of verification and validation of the Hubo-Ach system.

One of the keys to the team’s success is collaboration. The DRC-Hubo team consists of Drexel University, WPI, Georgia Tech, University of Delaware, Swarthmore, Purdue, Ohio State (check that) and RAINBOW (a company that rose from the Hubo Lab at Korea Advanced Institute of Science and Technology (KAIST)). Each partner would be responsible with one event. Efforts will then combine creating one master controller that is capable of doing all the given tasks. Having this unified framework gives them the ability to share their controllers without having to integrate their code.
Figure F.1: DARPA Robot Challenge Events. Pictures depict the Hubo2+ (KHR-4) preforming the eight given tasks. The photographs are meant to help you imagine that the robot is capable of preforming these tasks. The events are - Event 1: Driving an un-modified human vehicle; Event 2: Walking over rough, un-even terrain; Event 3: Removing debris from regions of interest; Event 4: Opening and navigating through multiple doors and hallways; Event 5: Climb an industrial ladder; Event 6: Break through a wall using un-modified human tools; Event 7: Turn a valve; Event 8: Replace a pump (note: this was replaced by a hose insertion task). All photographs were staged and taken by Daniel M. Lofaro. Picture montage taken from Dr. Paul Oh’s meeting to DARPA at the DRC Kickoff meeting, October 23-25, 2012.[63]
Appendix G. Balancing: Zero-Moment-Point (ZMP)

The past years of research in humanoids robotics has resulted in a stability criteria that must be followed for bipedal robots to stay stable. This is known as the Zero Moment Point criteria commonly referred to as ZMP [64]. ZMP is ubiquitous in the humanoid robotics community. The ZMP criteria states that a system is statically stable (balanced) if there is no moment acting on the connection between the end effectors touching the ground and the ground. This means that if the center of mass is over the support polygon there will be no moment. The support polygon is defined by the area formed by connecting the outer most portions of the end effectors (typically feet) that are touching the ground and/or walls, rails etc. If the zero moment point, the location of the center of mass (COM) projected in the direction of gravity, is located within this support polygon then the system is considered statically stable. Fig. G.1 gives an example of the zero moment point on a bipedal robot in a single support phase and a double support phase.

**Single Support Phase**: The single support phase of a bipedal robot is when a single foot is touching the ground. This creates a smaller support polygon.

**Double Support Phase**: The double support phase of a bipedal robot is when two feet of a bipedal robot are on the ground. This creates a larger support polygon. In addition there is a stable path that the ZMP can move from above one foot to the other. This allows the robot to guarantee stability
Figure G.1: Example of the zero moment point on a bipedal robot in a single support phase (bottom) and a double support phase (top). If the zero moment point, the location of the center of mass (COM) projected in the direction of gravity, is located within this support polygon then the system is considered statically stable.
while walking (static walking).
Appendix H. Balancing

Each of the methods used have to be stable through the motion in order for the system to be stable (i.e. not to fall down). The well known zero-moment-point (ZMP) criteria is what each method must adhere to in order to stay statically stable\[65\]. To handle perturbation an active balance controller was added. The active balance controller is applied on top of the pre-defined trajectories. Hubo is modeled as a single inverted pendulum with the center of mass (COM) located at length $L$ from the ankle. The compliance of the robot is composed of a spring $K$ and a damper $C$, see Fig. H.1. An IMU located at the COM gives the measured orientation.

The dynamic equation of the simplified model is assumed to be the same in both the sagittal and coronal plane.

$$mL^2\ddot{\theta} + C\dot{\theta} - K\theta = Ku$$ \hspace{1cm} (H.1)

This can be linearized and made into the transfer function:

$$G(s) = \frac{\Theta(s)}{U(s)} = \frac{K}{mL^2} \frac{s^2 + \frac{C}{mL^2} s + \frac{K-mgL}{mL^2}} \hspace{1cm} (H.2)$$

Prior work on the model and controller for the Hubo by Cho et. al. calculated $K=753 \ \frac{Nm}{rad}$ and $C=18 \ \frac{Nm}{sec}$ using the free vibration response method\[66\].

The control law is as follows
Figure H.1: Hubo modeled as a single inverted pendulum with COM located a distance $L$ from

\[ \theta^{xa} = \theta^{xa} + (K^x_p + sK^x_d) \left( \sum_{x \in t} \theta^x - \theta^c \right) \quad (H.3) \]

Where $\theta^t$ is the desired trajectory of the lower body (pitch or roll), $x$ denotes pitch or roll and $xa$ denotes pitch or roll on the ankle. $\theta^c$ is the orientation of the center of mass in the global frame. $\theta^n$ is the resulting trajectory. $K_p$ and $K_d$ are the proportional and derivative gains. The resulting control allows for a stable stance even with perturbations from upper body motions.

Fig. H.3 shows the example of the Hubo balancing using the above method.

Appendix J. Kinematic Planning Background

This section gives brief background of the methods used in this document Section J.1 and J.2 gives the background for the methods used for inverse kinematics and throwing on high DOF robots. This is the background to the development of the control system that made Hubo throw the first pitch at a Major League Baseball game in 2012 as seen in Section 3 and multiple examples given in Section 3.5. Finally Section G gives a brief description of the Zero Moment Point criteria which is used for humanoid walking and shown in the examples in Section 3.5.

J.1 Kinematic Planning

Kinematic planning focuses on creating and testing valid trajectories for series kinematic manipulators. The focus of this research is on high degree of freedom (DOF), high-gain, position controlled mechanisms. High-gain position controlled mechanisms are the focus because the experimental platform used for this work is a that type of robot. This limits the work because it is crucial that the joint-space acceleration profile is correct or the system will over-torque and shutdown.

The works are chosen as it pertains to end-effector velocity control. Throwing and hitting are examples of end-effector velocity control. The goal is to have the end-effector moving at a specific rate in a specific direction. In most cases it demands whole-body coordination to achieve a desired end-effector velocity. Whole-body coordination is different for planted robots
and un-planted robots.  
*Fixed robots* are robots where the base is attached to the ground or the base is significantly more massive than the manipulator. Planted robots do not have to worry about balance consternates. 
*Un-fixed robots* are robots that have a manipulator that is not significantly lighter than the base. In addition the robot is not physically attached to the ground. This results in the robot needing to satisfy balance constraints. In the static case if the robot satisfies the zero moment point (ZMP) criteria it will remain stable [67]. When the manipulator moves quickly, as in the case of pitching or throwing, such upper-body motions if not coordinated with the lower-body, can cause the humanoid to lose balance.

### J.2 End-Effector Velocity Control

End-effector velocity control (EEVC) is the act of moving your manipulator at a given speed through space at a given velocity. EEVC is being looked at as the mass of the end-effector does not change. Thus by controlling the velocity we also control the inertia. In addition I will be exploring EEVC as it pertains to manipulating objects. Through my research I have found that end-effector velocity control can be broken up into four major categories: *Time and location sensitive, location sensitive, time sensitive, and time and location insensitive.*

**Time and Location Sensitive:** If the velocity controller is time and location sensitive it means that your end effector needs
to have a given velocity at a specific time in a specific location or the task fails. Hitting a baseball with a bat is an example of *time and location sensitive* EEVC. If the bat has the correct velocity but not at the correct time it will not hit the ball or the ball will not go in the desired place. The same goes for if it does not have the correct location but does have the correct velocity. It is important to note that the manipulator only has instantaneous control over the object at the instant of contact. Other examples include playing the piano, hitting a tennis ball with a racquet, a moving soccer ball with a foot or any other task that requires to *hit a moving* object.

**Location Sensitive:** If the velocity controller is location sensitive it means that it only matters that the velocity occurs at a given location. The time it takes to reach that velocity will not effect the results. Hitting a nail with a hammer is a prime example of location sensitive EEVC. The nail is not moving but it does need to be hit in a given location with a given velocity. The vector of the velocity is determined by the required angle the nail needs to be hit at. In this example the nail is not time dependent and can be hit any time. Hitting it a \( t = N \) or \( t = N + 1 \) will not effect the results. It is important to note that the manipulator only has instantaneous control over the object at the instant of contact. Other examples of location sensitive end-effector velocity control are hitting a golf ball with a club, hitting a pool ball with the cue, and other activities that require a given location and direction of manipulation but are not time dependent.
**Time Sensitive**: If the location were the end-effector achieves a given velocity is not required to complete the task but the time when it happens is required it is considered *time sensitive* EEVC. This means that the end-effector can move in any region it desired as long as the end effector achieves a given velocity at a given time. The end-effector’s velocity can be dependent on the location achieved but the location is an independent variable and the velocity is the dependent variable. It is important to note that the manipulator control over the object during the entirety of the motion. This typically means that the manipulator is holding the object until the release stage. An example of this is throwing a baseball to first base to get someone out. Throwing the ball side arm, over arm, or even underarm does not matter as long as it is released at the correct time with the correct velocity to get it ball to the first-baseman to get the runner out. Other example of time sensitive EEVC are any other instance where an object is thrown within a given time.

**Time and Location Insensitive**: If the location and the time of when the end-effector achieves a given velocity does not matter it is considered time and location insensitive. The end-effector’s velocity can be dependent on the location achieved but the location is an independent variable and the velocity is the dependent variable. In this case the manipulator has control over the object until the release stage. Examples of this would be pitching a baseball, bowling, throwing a grenade or horseshoes etc. Throwing is an example of when the end-effector’s velocity holds a higher priority over the position.

Mechanisms with only a single degree of freedom are re-
stricted to throwing in a plane. 2-DOF mechanisms are able to throw in $R^3$ space with the correct kinematic structure. Such a mechanism can choose its release point or its end-effector velocity but not both. Mechanisms containing 3 or more DOF with the correct kinematic structure are able to throw in $R^3$ and choose both the release point and the end-effector velocity simultaneously.

In recent work Mori et al. [68] has show his ability to control the translational velocity, angular velocity and direction in a 2-dimension plane independently with a single DOF mechanism. The only input is torque to the manipulator. The concept consists is to map the input torque that will change only one of the kinematic variables and not the other two. This map is done over a given space and thus you can independently chose your translational and angular velocity as well as direction as long as it is in the valid search space.

Senoo et al.[69] used a torque controlled 3-DOF arm to create a high speed throwing trajectory. This arm falls into the *time and location insensitive* category of throwing. Senoo used a kinematic chain approach based on how humans throw. Doing this Senoo was able to achieved an end-effector velocity of 6.0 $m/s$ and can throw in $R^3$ space. This is done via the use of a planted robot arm made by Barret Technology Inc consisting of 3-DOF with a 360° rotation base yaw actuator.

Low degree of freedom throwing machines/robots are common. Typical throwing robots have between one and three degrees of freedom (DOF) [68, 70–80]. All of these mechanisms are limited to throwing in a plane.

These low degree of freedom throwing robots are either phys-
ically attached/planted to the mechanical ground or have a base that is significantly more massive then the arm.

Haddadin et al. [81] used their 7-DOF arm and a 6-DOF force torque sensor with standard feedback methods to dribble a basketball. In addition Zhikun et al. [82] used reinforcement learning to teach their 7-DOF planted robot arm to play ping-pong. Likewise Schaal et al. [83] taught their high degree of freedom (30-DOF) humanoid to hit a tennis ball using an on-line special statistical learning methods. Visual feedback was used in the basketball throwing robot by Hu et al. [84] achieving accuracy of 99%. All of the latter robots were fixed to the ground to guarantee stability.

Kim et al. [85, 86] takes the research to the next level with finding optimal overhand and sidearm throwing motions for a high degree of freedom humanoid computer model. The model consists of 55-DOF and is not fixed to mechanical ground or a massive base. Motor torques are then calculated to create both sidearm and overhand throws that continuously satisfies the zero-moment-point stability criteria [87].

The above works require forms of inverse kinematics. Most of the works use manipulators less then 6 or 7 DOF. This is because for those that have less then 6 DOF (7 DOF in some cases) closed form solutions can be solved for[44, 88–91].

For higher DOF IK solving methods such as Constrained Bi-directional Rapidly-Exploring Random Tree (CBiRRT) [92], neural nets[93–98] or learning methods[99] could be used. These methods do not guarantee any convergence and/or stability of the solution.

For high DOF IK to guarantee convergence if there is a so-
lution it is possible to use the inverse Jacobian transpose IK solving method[100–103]. Using this iterative method requires that there is only a small change from the end effector’s current position and the goal position. If the latter is the case, the solver will converge on a solution if one exists. It is important to note that the initial configuration must be known to obtain a solution.

The end-effector velocity control technique described in Section K.1 uses the principles of the inverse Jacobian transpose IK method along with forward kinematics and Lofaro et. al.[15] Sparse Reachable Map (SRM) to create a high DOF work space end-effector velocity controller.
Appendix K. Throwing

In early February 2012 the director of the Philadelphia Science Festival asked the Drexel Autonomous Systems Lab (DASL)\(^1\) if they could have their full-size humanoid Jaemi Hubo throw the ceremonial first pitch at the second annual *Science Night at the Ballpark*. On April 28th, 2012 Hubo successfully threw the first pitch at the Philadelphia Phillies vs. Chicago Cubs game, see Fig. K.1. According to the USA Today were 45,196 fans at the game and thousands more were watching it on television.

Hubo was the first full-size humanoid to throw the inaugural pitch at a Major League Baseball game. This task poses challenges in the area of fully-body locomotion, coordination and stabilization that must be addressed. This paper describes how the latter was done via the analyses/tests of three different approaches and the resulting final design. Section 2 gives a brief introduction to work already done in the field as well as states the requirements for the pitch. Section K describes the three different methods tested where: Section H discusses the balancing methods and criteria used. Section K.2 describes the human-robot kinematic mapping approach that uses a motion capture system to capture a human’s throwing motion then mapping that to a full-size humanoid. Section K.1 describes a fully automated approach that uses the sparse reachable map (SRM) to provide viable full body throwing trajectories with the desired end effector velocity[39]. Section K.3 describes the final method explored which is based on key-frame trajectories.

\(^1\)Drexel Autonomous Systems Lab: http://dasl.mem.drexel.edu
Figure K.1: Hubo successfully throwing the first pitch at the second annual Philadelphia Science Festival event Science Night at the Ball Park on April 28th, 2012. The game was between the Philadelphia Phillies and the Chicago Cubs and played at the Major League Baseball stadium Citizens Bank Park. The Phillies won 5-2.

Section L.1 describes the final design in detail and the modifications needed to make the robot’s pitch reliable. Finally Section L.2 gives final thoughts and possible improvements for future years.

K.1 Throwing Using Sparse Reachable Map

A Sparse Reachable Map (SRM) is used to create a collision free trajectories while having the end-effector reach a desired velocity as described in Lofaro et. al.[39]. The SRM has been shown to be a viable method for trajectory generation for high degree of freedom, high-gain position controlled robots. This remains true when operating without full knowledge of the
reachable area as long as a good collision model of the robot is available. The end-effector velocity (magnitude and direction) is specified as well as a duration of this velocity. The SRM is created by making a sparse map of the reachable end-effector positions in free space and the corresponding poses in joint space by using random sampling in joint space and forward kinematics. The desired trajectory in free space is placed within the sparse map with the first point of the trajectory being a known pose from the original sparse map.

\[ L_d(0) \in SRM \quad (K.1) \]

\( L_d(0) \) is known both in joint space and in free space. The Jacobian Transpose Controller method of inverse kinematics as described by Wolovich et al.\cite{104} is then used to find the subsequent joint space values for the free space points in the trajectory.

\[ q_1 = q_0 + \dot{q}_0 = q_0 + kJ^T e |_{x_0}^{x_1} \quad (K.2) \]

Where \( q_0 \) and \( x_0 \) is the current pose and corresponding end-effector position respectively. \( q_1 \) is the next pose for the next desired end-effector position \( x_1 \). Each desired end-effector position \( x \) must be within a euclidean distance \( d \) (user defined) from any point in the SRM.

\[ min(|x - SRM|) < d \quad (K.3) \]

If one of the points in \( x \) fails this criteria a new random point is chosen for \( L_d(0) \) and the process is repeated.

Each pose in the trajectory is checked against the collision
model to guarantee no self-collisions. The collision model is based on the OpenRAVE model of the Hubo platform called OpenHUBO, see Fig K.2.

Figure K.2: OpenHUBO - OpenRAVE model of Hubo KHR-4. Left: Collision Geometry. Right: Model with protective shells[39].

The commanded trajectory produces the desired velocity of 4.9 m/s at 60°. This was then tested on the OpenHUBO and on the Jaemi Hubo platform, Fig K.3 and Fig K.4 respectively.

To ensure balance throughout the motion the balance controller as described in Section H was applied and the static ZMP criteria was checked for the entire trajectory. This method worked as desired. In approximately 10% of the tests one or more joints would over torque and shutdown. This is due to the system not taking the robots power limitations into account.
Figure K.3: OpenHUBO running the throwing trajectory immediately after the setup phase is completed. $x_0$ is top left. Frames are read left to right and have a $\Delta t$ of 0.15s[39]

**K.2 Human to Humanoid Kinematic Mapping**

Motion capture (MoCap) systems are commonly used to record high degree of freedom human motion. Athletic trainers in baseball, football and cycling use motion capture to analyze and improve throwing and lower limb motions[105–108]. MoCap systems are also used to generate human-like motions and map those motion to humanoids[109, 110]. Fig. K.5 shows the Hubo’s kinematic structure (left) and the human (MoCap) kinematic structure(left). The human has 3-DOF at each joint while the humanoid has limited DOF at each corresponding joint. Some of the challenges in mapping between the human kinematic structure (from MoCap) to a humanoid’s kinematic structure are:
Figure K.4: Jaemi Hubo running the throwing trajectory immediately after the setup phase is completed. $x_0$ is top left. Frames are read left to right and have a $\Delta t$ of 0.15 sec.[39]

- The difference in the total degree of freedom (DOF).
- The difference in the kinematics descriptions.
- The different Kinematic constraints.

Gaertner et. al.[111] uses an intermediate model (Master Motor Map) to decouple motion capture data for further post-processing tasks. Our approach is to: a) Chose a set MoCap model. b) Preform motions where the pitch motions are decoupled (roll and yaw stays constant), avoids singularities and
robot joint position limitations. c) Combine joint values for nearby joints (reduce the model to the same DOF as the robot). d) Some tests require the addition of static offsets to joints to ensure the zero-moment-point (ZMP) criteria is satisfied as stated in Section H.

To test this method we used a human subject to throw a ball using upper and lower body movements. All motions were in the sagittal plane to keep pitch joints decoupled. To avoid the robot’s joint limit of ±180° an underhand throwing motion was used. Fig. K.6 shows the human throwing the ball and the robot throwing the ball to the mapped motion of the human.

To ensure balance throughout the motion the balance controller as described in Section H was applied and the static ZMP criteria was checked for the entire trajectory. The human subject threw the ball approximately eight feet (244 cm). The mapping of the latter motion caused the robot to throw the ball.
Video: http://danlofaro.com/phd/underarmthrow/

Figure K.6: (Left to Right): (1) Human throwing underhand in sagittal plane while being recorded via a motion capture system. (2) Recorded trajectory mapped to high degree of freedom model. (3) High degree of freedom model mapped to lower degree of freedom OpenHUBO. (4) Resulting trajectory and balancing algorithm run on Hubo.[112]
approximately five feet (152 cm). The discrepancy comes from the proportional difference in limb length from the human to the robot. A side by side video of the human and the robot throwing the ball is available for viewing on the this papers’s homepage².

K.3 Key-Frame Motion

Key-frame motion profiles for humanoids borrows from the animation industries’ long used techniques. When making an animation the master artist/cartoonist will create the character in the most important (or key) poses. The apprentice will draw all of the frames between the key poses. We borrowed this technique when we: posed the robot in the desired pose, record the values in joint space, and make a smooth motion between poses. In place of the apprentice, forth order interpolation methods were used to make smooth trajectories between poses. Forth order interpolation was used in order to limit the jerk on each of the joints. The resulting trajectory is a smooth well defined motion as seen in Fig. K.7.

To ensure stability throughout the motion the balance controller as described in Section H was applied and the static ZMP criteria was checked for the entire trajectory. The resulting end effector velocity was $4.8 \frac{m}{s}$ at the release point. Fig. K.8 shows the plot of the magnitude of the end effector’s velocity. It should be noted that at the instance of release the velocity vector is at an elevation of 40° from the ground.

²MoCap to Robot (Video): http://danlofaro.com/Humanoids2012/#mocap
Figure K.7: OpenHUBO using key-frame based method for throwing trajectory creation. Frames are read from top left to bottom right. Video of the above trajectory can be found at http://danlofaro.com/Humanoids2012/#keyframe
Figure K.8: Velocity vs. Time graph showing the magnitude of the end-effector’s velocity for the key-frame based throwing motion. The six different stages of pitching are also shown. Setup: move from the current position to the throw stance. Windup: end effector starts to accelerate from the throw stance and move into position for the start of the pitch state. Pitch: end effector accelerates to release velocity. Ball Release: the ball leaves the hand at maximum velocity \(4.8 \text{ m/s}\) at an elevation of 40° from the ground. Follow Through: reducing velocity of end effector and all joints. Reset: moves to a ready state for another throw if needed.
Appendix L. Sparse Reachable Map Velocity Space Inverse Kinematics

Low degree of freedom throwing machines/robots are common. Typical throwing robots have between one and three degrees of freedom (DOF) \[68, 70–73\]. All of these mechanisms are limited to throwing in a plane. Sentoo et al.\[69\] achieved an end-effector velocity of 6.0 m/s and can throw in \(R^3\) space using its Barret Technology Inc 4-DOF arm with a 360° rotation base yaw actuator. These low degree of freedom throwing robots are either physically attached/planted to the mechanical ground or have a base that is significantly more massive than the arm.

Kim et al. \[86\] takes the research to the next level with finding optimal overarm and sidearm throwing motions for a high degree of freedom humanoid computer model. The model consists of 55-DOF and is not fixed to mechanical ground or a massive base. Motor torques are then calculated that both allows for a sidearm or overarm throw and continuously satisfies the zero-moment-point stability criteria\[87\].

To create a valid throwing trajectory for a high-DOF, high-gain, position controlled robot, a desired line in \(R^3\) in the direction of the desired velocity must be created. Each point in the line is temporally separated by the robot’s command period \(T_r\). All points in this line must be reachable. Each point in the line must have poses that do not create a self-collision. A valid throwing trajectory is created when the latter criteria are met.
L.0.1 Self-Collision Detection

Self-collision is an important when dealing with a high DOF robot. Unwanted self-collisions can cause permanent damage to the physical and electrical hardware as well as causing the robot not to complete the given task.

![OpenRAVE model of Hubo KHR-4](image)

Figure L.1: OpenRAVE model of Hubo KHR-4. Left: Model with SRM of right arm. Center: SRM (blue) with setup and velocity phase trajectories (green) Right: Collision Geometry

To aid in the detection of self-collisions a detailed model of the Hubo KHR-4 was made in the widely used open-source robot simulation environment OpenRAVE[16]. The model was created by exporting the three dimensional schematics that the physical robot was created with, to a format that OpenRAVE can use. This was done in order to ensure an accurate and detailed model. For these experiments we needed the external boundaries only; the internal geometry was replaced with a simplistic representation. The external shell is the only part
now visible, see Fig L.1 (Center). The Proximity Query Package (PQP) was used to detect collisions between any two pieces of the robot’s external shell. Due to the high polygon count of the external shell the computation time of detecting a collision was on the magnitude of seconds. It is advantageous to reduce this time if the system is to run live on the robot. Computation time is decreased significantly when boundary/collision geometries are simplified due to the lower polygon count. The collision geometries were further simplified to decrease computation time by making them primitives such as spheres, cylinder and boxes, see Fig L.1 (Right).

Joint limitations are added to the model to mimic the physical robot. The model can be commanded the same configurations as the physical robot. A pose is commanded to the model, PQP searches for any collisions. With the simplified collision geometry self-collisions are detected on the order of milliseconds. If there are no collisions then the pose can be applied to the physical robot. A 5% increase in volume between the simplified collision geometry and the high polygon geometry was added to ensure all of the physical robot’s movements will not collide due to minor calibration errors.

L.0.2 Reachable Area

The desired end-effector velocity must be achieved with all joint limits and self-collision constraints satisfied at all times. Typical methods of determining reachability is to move each joint through its full range of motion for each DOF[113, 114]. Due to the high DOF of the Hubo KHR-4 this method is not
A sampling method described in this work is similar to Geraerts et al.\[115\]. It was used to accommodate the high DOF system. Both active and static joints must be defined to calculate the reachable area of a manipulator at a discrete time $N$. The static joints are assumed to hold a fixed position at time step $N$. Active joints are free to move to any position as long as it satisfies the joint angle limitations and does not create a self-collision. A uniform random number generator is used to assign each active joint with an angle in joint space. Each random angle assigned is within the valid range of motion of the respective joint. The self-collision model described in Section L.0.1 is used to determine the self-collision status with the randomly assigned joint angles. If there is no self-collision the end-effector position and transformation matrix $T$ are calculated using forward kinematics.

$$\chi_i = \begin{bmatrix} R_i & \Gamma_i \\ 0 & 1 \end{bmatrix}$$  \hspace{1cm} (L.1)

$$T = [\chi_1 \cdot \chi_2 \cdot \ldots \cdot \chi_n]$$  \hspace{1cm} (L.2)

where $\chi_i$ is the transformation between joint $i - 1$ and $i$, $R_i$ is the rotation of joint $i$ with respect to joint $i - 1$ and $\Gamma_i$ is the translation of joint $i$ with respect to joint $i - 1$, and $n$ is the number of joints in the kinematic chain.

The end-effector position and the joint angles used are recorded. This process is repeated multiple times to form a sparse representation of reachable end-effector positions in $\mathbb{R}^3$ and the corresponding joint angles in joint space. The resulting representation is called the Sparse Reachable Map (SRM). Fig. L.2
shows a cross section of the SRM about the right shoulder between -0.40 m to 0.40 m on X, -0.40 m to 0.40 m on Z, and -0.21 to -0.22 m on Y. The blue points show valid end-effector locations with known kinematic solution in joint space. Fig. L.1 shows the SRM of the entire right arm. The SRM is used to calculate valid movement trajectories.

Figure L.2: Cross section of the SRM about the right shoulder between -0.40 m to 0.40 m on X, -0.40 m to 0.40 m on Z, and -0.21 to -0.22 m on Y. (Blue) show valid end-effector locations with known kinematic solution in joint space. (Red) Commanded right arm end-effector position in $R^3$. (Green) The logged joint space values converted to $R^3$ using forward kinematics.
L.0.3 Trajectory Generation

An end-effector velocity, $\vec{V}_e$, is chosen based on target location, the well known equations of projectile motion, and the required velocity duration $t_e$. $\vec{V}_e$ must be held for a time span of $t_e$. The release point must be within the time span $t_e$. The magnitude of the velocity in the direction of $\vec{V}_e$ immediately preceding time span $t_e$ must be less than or equal to the magnitude of $\vec{V}_e$ during $t_e$. $t_e$ must be an integer multiple of the robot’s actuator command period $T_r$.

A line $\vec{L}_d$ in $\mathbb{R}^3$ that passes through $(X_0, Y_0, Z_0)$ in the direction of $\vec{V}_e$ is created. $\vec{L}_d$ is the discrete representation of $\vec{L}_d$. Each point in $\vec{L}_d$, $(X_0, Y_0, Z_0), (X_1, Y_1, Z_1) \cdots (X_n, Y_n, Z_n)$, are separated by a time span $T_r$.

The desired velocity is defined as

$$\vec{V}_d = [V_x \hat{i}, V_y \hat{j}, V_z \hat{k}]$$ (L.3)

The line $\vec{L}_d(n)$ is defined as

$$\vec{L}_d(n) = [X_n \hat{i}, Y_n \hat{j}, Z_n \hat{k}]$$ (L.4)

where $n$ is the current zero based time step index value for the time span $t_e$. The change in $\vec{L}_d$ between time step 0 and $n$ must be equal to our desired velocity $\vec{V}_d$.

$$\frac{\Delta \vec{L}_d|_0^n}{n \cdot T_r} = \vec{V}_d$$ (L.5)

thus

$$\vec{V}_d = \frac{\vec{L}_d(n) - \vec{L}_d(0)}{n \cdot T_r}$$ (L.6)
The line $\vec{L}_d$ at time step $n$ can now be defined in terms of $\vec{V}_d$, $T_r$, the origin $\vec{L}_d(0)$, and the current zero based time step index value $n$.

$$\vec{L}_d(n) = n \cdot T_r \cdot \vec{V}_d + \vec{L}_d(0) \tag{L.7}$$

where

$$\vec{L}_d(0) = [X_0, Y_0, Z_0] \tag{L.8}$$

The line $\vec{L}_d$ is the trajectory the robot’s end-effector must follow during the time span $t_e$. The starting point $\vec{L}_d(0)$ must be found so that $\vec{L}_d$ is within the reachable area. $\vec{L}_d(0)$ is set to a random starting points chosen within the SRM.

$$\vec{L}_d(0) \in SRM \tag{L.9}$$

All subsequent points in $\vec{L}_d$ must fall within some Euclidean distance $d$ from any point in SRM. If one of the points in $\vec{L}_d$ fails this criteria a new random point is chosen for $\vec{L}_d(0)$ and the process is repeated.

Once an $\vec{L}_d$ is found that fits the above criteria the inverse kinematic solution must be found for each point and checked for reachability. Smaller values of $d$ will increase the probability $\vec{L}_d$ is within the reachable area defined in the SRM however more iterations will be required to find a valid $\vec{L}_d$. Larger values of $d$ will decrease the number of iterations needed to find a valid $\vec{L}_d$ however the probability of $\vec{L}_d$ being in the reachable area is decreased. In addition larger values of $d$ decreases the system’s ability to properly map near sharp edges in the SRM. Increasing the number of samples in the SRM will allow for larger values
L.0.4 Inverse Kinematics

The trajectory $\vec{L}_d$ has one point with a known kinematic solution in $\mathbb{R}^3$ and in joint space, $\vec{L}_d(0)$. The joint space kinematic solutions for points $\vec{L}_d(1) \rightarrow \vec{L}_d(n)$ are unknown. Mapping the robot’s configuration $\vec{q} \in Q$ to the desired end-effector goal $\vec{x}_g \in X$, where $Q$ is the robot’s configuration space and $X$ is in $\mathbb{R}^3$, is done using Jacobian Transpose Controller used by Weghe et al.[116]. Weghe shows the Jacobian as a linear map from the tangent space of $Q$ to $X$ and is expressed as

$$\dot{\vec{x}} = J\dot{\vec{q}} \quad (L.10)$$

The Jacobian Transpose method is used because of the high DOF of the Hubo KHR-4. Under the assumption of an obstacle-free environment the Jacobian Transpose Controller is guaranteed to reach the goal. A proof is shown by Wolovich et al.[104].

To drive the manipulator from its current position $\vec{x}$ to the goal positions $\vec{x}_g$ the error $\vec{e}$ is computed and the control law is formed.

$$\vec{e} = \vec{x}_g - \vec{x} \quad (L.11)$$

$$\dot{\vec{q}} = kJ^T \vec{e} \quad (L.12)$$

where $k$ is a positive gain and self-collisions are ignored. The instantaneous motion of the end-effector is given by
\[
\dot{\vec{x}} = J\dot{\vec{q}} = J(kJ^T\vec{e}) \quad (L.13)
\]

The final pose $\vec{q}$ for our goal position $\vec{x}_g$ can now be found.

The Jacobian Transpose method works best when there is a small difference between the current position $\vec{x}$ and the goal position $\vec{x}_g$. $\vec{L}_d(0)$ is known both in $X$ and in $Q$ and is the starting point.

\[
\vec{x} = \vec{L}_d(0) \quad (L.14)
\]

\[
\vec{q}_0 = SRM \left( \vec{L}_d(0) \right) \quad (L.15)
\]

The goal position $\vec{x}_g$ is set to the next point in $\vec{L}_d$

\[
\vec{x}_g = \vec{L}_d(1) \quad (L.16)
\]

The pose $\vec{q}_1$ can now be calculated

\[
\vec{q}_1 = \vec{q}_0 + \dot{\vec{q}}_0 = \vec{q}_0 + kJ^T\vec{e}|_{\vec{x}_g} \quad (L.17)
\]

where $\vec{x}_g = \vec{L}_d(0)$ and $\vec{x} = \vec{L}_d(1)$. $\vec{L}_d(1)$ is now known both in $X$ and in $Q$. Now $\vec{x} = \vec{L}_d(1)$ and the process is repeated until all points in $\vec{L}_d$ are known both in $X$ and $Q$.

**L.0.5 On-Line Trapezoidal Motion Profile**

The robot’s starting position $\vec{x}_0$ is not guaranteed to be the same as the first point in the velocity trajectory $\vec{L}_d$. To avoid over large accelerations when giving this step input from $\vec{x}_0$ to $\vec{L}_d(0)$ an on-line trapezoidal motion profile (TMP) was used to
generate joint space commands with the desired limited angular acceleration and velocity. The TMP was only active during the setup phase where the robot’s end-effector moves from \( \vec{x}_0 \) to \( L_d(0) \). This is because the TMP’s inherent nature has the potential to adversely effect the desired velocity in \( R^3 \) under high angular velocity and acceleration conditions in joint space.

The TMP was designed to limit the applied angular velocity and acceleration in joint space and to prevent over-current/torque. An important advantage over simply limiting output velocity and acceleration is that the TMP has little to no overshoot. When a clipped and rate-limited velocity profile is integrated, the resulting position trajectory may over or undershoot due to this non-linear system behavior. The TMP accounts for the imposed limits inherently, and will arrive at a static goal without overshoot. Table L.1 describes the three regions that make up the TMP.

<table>
<thead>
<tr>
<th>Region 1</th>
<th>Accelerate at maximum acceleration in direction of goal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region 2</td>
<td>Achieve and hold maximum velocity</td>
</tr>
<tr>
<td>Region 3</td>
<td>Decelerate to zero velocity to reach goal</td>
</tr>
</tbody>
</table>

The area under the velocity trapezoid in region 1-3 is the total displacement achieved by the profile. By shaping this profile based on initial and goal conditions, any goal position can be precisely reached, even if velocity clipping occurs. The shape of the profile can be challenging to identify, since it is not always a trapezoid. For large velocity and acceleration limits
and small displacements, the profile will only reach a fraction of maximum velocity, and will be triangular. The varying shape of the profile means that calculating and storing complete motion profiles for each update may be required. This paper’s method removes the need for complete profile generation and storage.

Regions one and two of the velocity profile are bounded by the maximum acceleration, $a_m$, and maximum velocity, $v_m$, respectively. In these regions the joint moves towards the goal as fast as the limits allow. In region three the joint has reached a deceleration distance $d_s$ from the goal. It now accelerates at $-a_m$. When the velocity reaches zero, the joint has exactly arrived at the goal position. $d_d$ is the integral of the velocity profile in region three, given by (L.18).

As long as the distance to the goal $d_g$ and $d_s$ are equal then the controller needs to decelerate at the maximum rate to come to rest at the goal. Conversely, for the current goal distance, there is a critical velocity $v_c$ such that, if the joint began moving at this velocity in the following time-step $\tau$, it could decelerate at $a_m$ to reach the position goal. The controller minimizes the error between $v_c$ and $v_0$ at each time-step.

Since the joint is moving with velocity $v_0$ during a current time-step, some initial distance $d_i$ (L.19) is traveled before the joint can be affected. Defining $\hat{u}$ as the sign of the distance to the goal, $v_c$ is related to $d_g$ and $d_i$ quadratically in (L.21). This equation assumes simple trapezoidal integration. Solving for $v_c$ using the quadratic formula generally produces complex roots due to the possibility of negative $v_0$ or $d_g$. In (L.22), $v_0 \cdot \hat{u}$ is the current velocity relative to the goal direction, producing a positive term if the signs of both terms match. This result will
always produce a real value for \( v_0 \) and \( d_g \).

\[
d_s = \frac{v_0^2 \text{sign}(v_0)}{2a_m} \tag{L.18}
\]

\[
d_i = v_0 \tau + \frac{v_c - v_0}{2} \tau \tag{L.19}
\]

\[
\hat{u} = \text{sign}(d_g) \tag{L.20}
\]

\[
v_c^2 = 2a_m (d_g - d_s) \tag{L.21}
\]

\[
v_c = \hat{u}a_m \left( \sqrt{\frac{a_m \tau^2}{4} - 4\hat{u}v_0 \tau + 8|d_g|}{4a_m} - \frac{\tau}{2} \right) \tag{L.22}
\]

### L.1 Final Design

The final goal is the have an end-effector velocity of \( 9.47 \frac{m}{s} \) at \( 45^\circ \). The key-frame method was tested to throw at \( 4.8 \frac{m}{s} \). To increase the end-effector velocity the upper body motion was kept unchanged but the lower body added a stepping motion with its legs. The stepping motion consists of lifting the left foot up, pushing forward with the right and move the left forward 10 cm. Stepping with your non-dominant foot, and pushing with the dominant, when throwing overhand is common practice to increase the distance you can throw a ball. Jaemi Hubo throws with its right hand and steps with its left. This increased the end-effector velocity from \( 4.8 \frac{m}{s} \) to \( 7.1 \frac{m}{s} \). Fig. L.3 shows the stepping motion of the robot.
Figure L.3: Hubo stepping 10 cm up and forwards increasing the end effector velocity by 2.3 $\frac{m}{s}$.

The addition of pushing off with the right foot and stepping forward introduced two problems. 1) The ZMP criteria is not satisfied throughout the motion and 2) the right foot would slip when pushing its body forward. To avoid slip *hook and loop* was paced on the bottom of the right foot (non-dominant) and on the throwing platform. This did not permanently attach the robot to the platform but it did allow for more friction between the foot and the ground. This allowed the balancing controller to function adequately for the short step and maintain stability. The platform was added to ensure a more consistent ground for the robot to balance on than the baseball field can inherently provide.

An additional 2.5 $\frac{m}{s}$ was needed to give a proper throw. Bor-
rowing from the GRASP Lab and their high powered pneumatic wrist on their PhillieBot, a spring loaded mechanism was added to Hubo’s wrist, see Fig. L.4. The addition of this mechanism allowed the robot to achieve an end-effector velocity magnitude of 10 m\(s\). Fig. L.5 shows a frame overlay of the the Hubo throwing a regulation baseball 10 m (32.8 feet). Fig. K.1 shows the same throw at Citizens Bank Park on April 28\(^{th}\), 2012.

L.2 Conclusion

Throwing using the key-frame based method was the most reliable and successful. The system was open-loop in respect to the location where it would throw the ball. This is why it over threw the ball during the real pitch, see Fig. L.5. The lessons learned when performing the throwing task is that

1. A unified algorithmic framework is needed for three tier testing
Figure L.5: (TOP) Pitch at Phillies Game. (BOTTOM) Practice pitch at Drexel. Frame overlay of the Hubo throwing overhand a distance of 10 m (32.8 feet) with a release angle of 40° and a tip speed of $10 \text{ m/s}$. Captured at 20 fps with a shutter speed of 1/30 sec. Each of the white dashes of in the image is the actual baseball as picked up by the video camera.

2. Using such a framework the loop has to be closed on the ball’s final location

3. System for having a stable landing when taking a step

Section 3 describes the unified framework that answer #1 above. As stated before throwing is a full body locomotive task. Section 5.2 closes the loop using visual methods. This shows how the unified algorithmic architecture can be used for
visual servoing a full body locomotive tasks. This visual servoing example answers #2 above. The use of active damping as seen in Section 5.3 allows the robot to land on the ground. This answers #3 above.
Appendix M. Validation: Peer Survey on Hubo-Ach

This section shows the peer survey taken by users of Hubo-Ach. Thirteen independent users were surveyed. The overwhelming conclusion was that the system is useful, was the unifying algorithmic framework as advertised and helped with development. Out of a score from 0-10 on the question "Would you use Hubo-Ach again the the future when programming Hubo" received an average of 9.23 (see Table M.11. Table M.1, M.3, M.5, M.7, M.9, M.11).
